8 There is an apparent immediate need for informing the various industrial plants as to what to do with a veteran who has either an emergency illness or needs medical or welfare help. A circular giving the names of the local agencies and phone numbers of the persons in charge of these local agencies is suggested. Such a circular could be issued by the Veterans' Administration service. Such an agency should be in operation now.

URINARY RETENTION FOLLOWING SURGICAL OPERATION ON THE RECTUM AND SIGMOID

TREATMENT BY TRANSURETHRAL RESECTION

JOHN L. EMMETT, M.D.

AND

DAVID S. CRISTOL, M.D.

Fellow in Urology, Mayo Foundation
ROCHESTER, MINN.

Among the complications which may follow surgical procedures to remove the rectum or sigmoid, none is more disturbing to the patient and to the surgeon than persistent urinary retention. The most common types of operations employed on this portion of the bowel are posterior resections or combined abdominoperineal resections (either one stage or two stage procedures). These operations are usually done for cancer which involves the rectum or sigmoid. The urologic problem involved after one of these operations has been performed is difficult. It consists chiefly in relieving the urinary retention and keeping the degree of urinary infection at a minimum.

The vesical dysfunction that may follow the operations mentioned in the preceding paragraph may express itself from a moderate difficulty of micturition with varying amounts of residual urine to complete inability of the patient to void, with total urinary retention. An attempt to explain the reason for this phenomenon has elicited much discussion. The most frequently accepted explanation has suggested operative injury to parasympathetic nerves which control the urinary bladder. However, studies with cystometrograms by Collier and Eastman¹ have failed to substantiate this hypothesis. Other explanations suggest edema of the prostatic or membranous urethra incident to the trauma of operation or decompensation of a previously compensated bladder embarrassed by some obstruction of the vesical neck. The weakening of the bladder has usually been ascribed to injury of nerves. Engel² has emphasized the fact that many of the male patients may have suffered from minimal degrees of prostatism for some time previous to operation. He has called attention to the

fact that most of the male patients on whom this type of operation is performed are in the age of prostatism. It is also common knowledge that other events in the life of a patient suffering from prostatism, such as alcoholic or sexual excess, overeating, chilling or surgical operations the site of which is well removed from the vicinity of the bladder and the prostate gland, may serve to precipitate urinary retention.

Transient difficulties following operations well removed from the bladder or urethra are difficult to explain in the light of our present theories of the physiology of micturition. This is especially true when they occur in young patients who have no degree of obstruction of the vesical neck or the urethra. Persistent difficulty, however, that continues for weeks or months in older patients does not present a puzzling diagnostic or therapeutic problem if it is considered in its simplest elements.

The key to the solution of this distressing postoperative complication is found in the past ten years' experience with transurethral resection for urinary obstruction. Previous to the modern era of transurethral resection, large numbers of patients suffering from urinary retention (unassociated with any surgical operation) were dismissed with a diagnosis of "cord bladder" or "atypical cord bladder." The reason for this diagnosis was that no obstruction at the vesical neck could be seen on cystoscopy and no palpable enlargement of the prostate gland was apparent on digital rectal examination. As experience in the field of transurethral resection increased, it became possible to recognize minimal degrees of obstruction of the vesical neck which theretofore had been missed entirely. This has become so important that no experienced transurethral surgeon will now state that there is no obstruction at the vesical neck until resection has actually been attempted. It is common experience that, after two or three pieces of tissue have been removed from the anterior quadrant at the vesical neck, lateral lobe tissue near the apex of the prostate not previously apparent will "roll" toward the midline and appear very obstructive. Urinary retention of "obscure etiology" has therefore resolved itself not so much into a problem of determining the strength of the detrusor and of the means of improving its tone as into a simple problem of imbalance between the detrusor and the vesical neck.³ No matter how weak the detrusor, if the vesical neck can be weakened sufficiently by transurethral resection the bladder should be able to empty completely. Applying these principles to patients suffering from urinary retention following operations on the rectum and sigmoid, this postoperative complication has ceased to be a problem of importance.

In our earlier experience we approached this problem rather cautiously, especially in cases in which there had been no previous history of urinary difficulty. As experience increased, however, it was realized that nearly all of these male patients, being in the age of prostatism, had some degree of obstruction of the vesical neck even though of a mild degree. We were also happily surprised to find that almost all could be relieved of their urinary retention immediately by transurethral resection. We are presenting here a study of these cases in which resection has been performed.

PRESENTATION OF STUDY OF CASES

In the group of cases presented here we have included those in which transurethral resection was done after removal of the rectum or sigmoid for carcinoma. We have excluded from this study cases in which urinary obstructive symptoms were prominent previous to the rectal operation and in which the necessity of transurethral resection was recognized but it was elected to

proceed with the intestinal operation prior to operation on the prostate. In looking over our records of the past ten years we have found 33 cases which would meet the requirements and they form the basis for this study. The types of major surgical procedures done on these patients are recorded in table 1. It will be noticed that most of these were either posterior resections or combined abdominoperineal resections. The site of the malignant growth varied from 2 to 12 cm above the anal margin. The age of these patients (table 2) varied from 37 to 75 years, but the majority (29) were more than 50 years of age, while all but 1 were more than 40 years of age. It may be said, therefore, that practically all of the patients are in the age of prostatism.

Preoperative Data—In 24 of these cases no urinary symptoms of any kind were elicited in the history prior to the intestinal operation. In 6 there were symptoms which were so minimal that the question of obstruction of the vesical neck was not given consideration. In 3 cases the symptoms were a little more pronounced than in the other cases. In only 4 of the 33 cases did the symptoms seem to justify a determination of the residual urine. In 2 cases there was no residual urine and in the remaining 2 the amounts of residual urine found were 25 and 140 cc respectively. Microscopic examination of centrifuged specimens of urine prior to the intestinal operation disclosed that in 30 cases the urine either was negative or contained less than 10 leukocytes

per high power field. In 3 cases moderate amounts of pus were encountered. An examination of the records of these patients to determine how many had evidence of prostatic enlargement on digital rectal examination was somewhat disappointing. The reason for this, however, is that in many cases the rectal growth is of such size and in such a position that it makes accurate palpation of the prostate gland difficult or entirely impossible. In 18 of these 33 cases there was no preoperative description of the prostate by digital rectal examination. In 6 cases the prostate gland was

reported to be normal in size and consistency, in 5 it was enlarged 1 (on a basis of 1 to 4, in which 1 designates the least and 4 the greatest enlargement) and in 3 it was enlarged 1+ while in 1 other it was described as enlarged 2.

Postoperative Data—After the operation on the bowel, the urinary complications in these cases were quite similar. In all cases symptoms of urinary retention developed. Most patients were unable to void at all, while others were able to void small quantities of urine, but large quantities of residual urine persisted. Intermittent or indwelling catheterization was necessary in these cases, so that in nearly all pyuria developed in spite of urinary antiseptics. The most common organism found in the urine when cultured was *Streptococcus faecalis*, which was present in pure culture in 13 cases and was associated with other organisms in 6 more.

In most of these cases conservative measures of various types were employed in an effort to stimulate the

bladder. They included subcutaneous injections of the choline drugs such as methylol chloride and carbamylcholine chloride (doryl) and neostigmine (prostinigmine) and lavage of the bladder with irritating solutions such as 1 per cent solution of mercurochrome and 1/750 gentian violet. None of these procedures proved effective in these cases. The time interval that elapsed between the intestinal operation and the transurethral resection is shown in table 3. It will be seen that nearly all of these patients were given a period of more than three weeks to allow the bladder to recover. Almost a third of the group were allowed to go more than two months, but most of these cases occurred during the earlier period when we were not so well acquainted with the possibilities of transurethral resection in such cases as we are now. We have now become so confident that most of these patients can be relieved in this manner that we do not advise waiting longer than three weeks, unless the patient's general condition is not satisfactory.

The cystoscopic findings in these cases are interesting. In the majority the most prominent finding is a rather deep bas-fond with a "sagging" type of bladder which gives the appearance that the supporting struc-

tures in the region of the base of the bladder are gone. It has been our feeling that this lack of support, rather than the disturbance of the nerve supply of the bladder, is one of the greatest factors in the vesical atony. Another reason in favor of this hypothesis is that we have yet to encounter an "autonomous" type of bladder such as is seen in animals after experimental section of both pelvic nerves or in man after traumatic destruction of the sacral portion of the spinal cord or of the cauda equina. It seems improbable that in every case only the sensory fibers of the pelvic nerves should be disturbed with a resulting "atonic" bladder. The cystometric studies of Collier and Eastman¹ would also lend support to this reasoning.

An accurate cystoscopic evaluation of the vesical neck is extremely important, as herein lies the solution of the entire problem. In 17 of the 33 cases under discussion cystoscopy was performed prior to resection, while in 16 it was performed only at the time of resection. From the cystoscopist's description of the vesical neck one gains the impression that there was no visible evidence of obstruction in 13 cases, a minimal amount of obstruction in 16 cases and a moderate amount of obstruction in only 4 cases. In spite of the cystoscopic appearance of the vesical neck transurethral resection was performed on all of these patients. The amount of prostatic tissue removed in each case is shown in table 4. It will be noticed that in 17, or half of the cases, less than 10 Gm of tissue was removed while in only 6 cases was it necessary to remove more than 20 Gm. It is interesting to try to correlate the amount of tissue removed with the preoperative cystoscopic description of the vesical neck. In 12 cases the cystoscopic findings and amount of tissue removed seemed to be proportional. In 3 cases the amount of tissue removed was less than one would have suspected from the cystoscopic description, while in 18 cases the amount of tissue removed at resection greatly exceeded the amount suggested to be present at cystoscopy. In 31 of the 33 cases microscopic examination of the tissue removed showed it to be benign adenofibromatous hyperplastic tissue. In 1 case the bulk of the tissue was benign with one small region of adenocarcinoma. In another case the tissue proved to be secondary extension from the carcinoma of the bowel.

Results—The results of transurethral resection in these cases have been exceptionally good. In 30 cases they are regarded as excellent, which means that normal vesical function returned and the residual urine was completely eliminated. In 1 case the result has been fair. This patient was 51 years of age. His difficulty following the intestinal operation consisted of nocturnal enuresis and residual urine of 50 cc. His residual urine was eliminated by transurethral resection, but the nocturnal enuresis continues. It seems quite possible that there may be some impairment of the nerve supply of the bladder or urethral sphincter in this case. In 2 cases the results were poor. One patient was a man aged 69 who had an extension of the cancer to involve the seminal vesicles. He died from metastasis seven and a half months after resection. The other patient was a man aged 37. Little if any tissue could be removed (a total of 2 Gm). No patients died after operation.

COMMENT

It is our opinion that the problem of urinary retention in the male patient after operations on the rectum and sigmoid is not as complex as has been heretofore supposed. Reduced to its basic components it may be

stated simply. Most patients subjected to this type of operation are in the age of prostatism. It has been recognized for years that many factors, such as chilling, alcoholic or sexual excess, overeating or surgical operations on other parts of the body, will precipitate urinary retention in such cases. Trauma to the prostate and urethra plus the removal of the supporting structures around the base of the bladder (such as occurs after posterior resection or combined abdominoperineal resection) furnishes an ideal situation for the bladder to "decompensate" and become unable to expel urine through a moderately obstructed vesical neck. Instead of attempting to increase the vesical tone (which is impossible to do by any means available at present) the rational procedure is to weaken the vesical neck and obviate the imbalance that exists between the detrusor and the vesical neck. This can be easily accomplished by transurethral prostatic resection and will completely and quickly relieve nearly all patients suffering from this annoying condition. To avoid unnecessary operations it is probably best to allow the patient a period of at least three weeks after the intestinal operation to regain his vesical function before one advises transurethral resection.

ORNITHOSIS AS A CAUSE OF SPORADIC ATYPICAL PNEUMONIA

PHILADELPHIA

With the increasing incidence of primary atypical pneumonia in recent years it has become desirable to establish an etiologic diagnosis whenever possible. It is only during the past decade that this disease has come to be recognized as a definite clinical entity. Numerous reports concerning this condition are to be found in the current literature, most of which have come out of military establishments. Owen¹ reviewed the literature concerning primary atypical pneumonia and noted that over 1,750 cases had been reported from military posts since 1935. To these he added another 738 cases occurring at Scott Field during 1942. He also was able to find over 1,100 cases originating from civilian sources. It is significant that most of the reports available are concerned with epidemic outbreaks of the disease showing seasonal variations, being most frequent in the spring and late fall.

Atypical pneumonia occurs in a sporadic form as well as in an epidemic one. In both forms attempts to isolate an etiologic agent with ordinary laboratory procedures are usually unsuccessful. During the past two years we have observed 6 sporadic cases of atypical pneumonia occurring in the Philadelphia area in which we were able to confirm the diagnosis of ornithosis by means of the complement fixation test. During this period we observed a fair number of cases of atypical

From the Medical Services of Abington Memorial Hospital, Abington, Pa., and Presbyterian Hospital, Philadelphia.

Dr. K. F. Meyer of the University of California made it possible for the complement fixation studies to be performed.

¹Owen, C. A. Primary Atypical Pneumonia. *Arch. Int. Med.* 73: 217 (March) 1944.

pneumonia. Unfortunately, it was possible to perform the complement fixation test for ornithosis in only a limited number of cases in which the diagnosis was suspected by reason of a history of contact with pigeons or through the nature of the clinical course.

In 1941 Meyer² first reported the isolation of a virus similar to that of psittacosis from the lung of a patient who had a history of exposure to a flock of racing pigeons. Of 33 pigeons in the flock, 19, or 63 per cent, were found to have a positive complement fixation titer in their serums, and in 4 pigeons a virus which was indistinguishable from that of the patient was isolated. About this time Meyer and his co-workers³ suggested that the term psittacosis be reserved for those cases of human infection occurring after contact with psittacine birds such as parrots, parakeets, lovebirds and canaries and that the term ornithosis be applied to infections following exposure to doves, pigeons, chickens and the like.

Late in the nineteenth century Ritter⁴ in Switzerland first described psittacosis as a pneumonic infection occurring after contact with tropical birds. Since that time the disease has become increasingly recognized and sporadic outbreaks have been reported in various countries. Human infection has been traced to parrots, parakeets, finches, arctic fulmar, doves and chickens and in 1941 Meyer first incriminated the pigeon. In 1942 he reported that 10 cases of human atypical pneumonia with two deaths could be traced to exposure to different species of pigeons, these cases being distributed among several states. Favour⁵ in 1943 reported 3 cases of ornithosis confirmed by means of the complement fixation test. A history of contact with pigeons was obtained in 1 case, a sick canary in the second and there was no history of any direct contact in the third. Smadel⁶ in 1943 studied 45 cases of sporadic atypical pneumonia occurring among large eastern urban populations. In these cases he was able to make a definite diagnosis in 10 instances by means of the complement fixation test. Six of these gave a history of contact with or proximity to pigeons. Smadel reached the conclusion that approximately one fourth of the sporadic cases of atypical pneumonia are due to infection by the virus of psittacosis (ornithosis). Recently Meikeljohn, Beck and Eaton⁷ reported 10 cases of ornithosis which they had collected over a four year period. In all these cases the diagnosis was confirmed by isolation of the virus and through serologic means. Four of their cases were naturally occurring with a history of pigeon contact, 3 were in nurses who had contracted the disease from infected patients, and the last 3 were laboratory infections. Four of these cases were very severe and had a fatal termination.

CLINICAL FEATURES OF ORNITHOSIS

Method of Transmission—It is believed that infections in human beings usually originate from contact with material containing the virus which has been excreted by an infected bird. The point of entry is thought to be the respiratory tract. Although in most

cases which have been heretofore reported there is usually a history of direct contact with infected birds, it is significant that infected droppings may be blown about by air currents as dust. In this manner it is possible to produce human infection without direct contact and theoretically at sites remote from the home of the infected bird. It is our belief that the latter form of infection, in which there is no history of actual contact, may be responsible for some sporadic cases of endemic atypical pneumonia which pass unrecognized. Transmission of the disease from one human being to another has been known to occur. Meikeljohn and his collaborators⁷ observed that in 5 cases of psittacosis 3 occurred in nurses who acquired the infection from the 2 original patients.

Incubation Period—The time interval between exposure and the onset of the acute illness is usually given as eight to fourteen days. Unfortunately, in many of the cases it is impossible to determine the incubation period as there is often no history of contact, or, on the other hand, in the case of pigeon fanciers the patient has been in daily contact with the birds for a considerable period of time.

Symptomatology—In most cases the onset is abrupt, with a rapid rise in temperature to 103 to 105 F.

The findings have been described as being characteristic of the typhoidal state. The complaints are not dissimilar to those seen in any acute infection, namely malaise, anorexia, backache, headache and muscle pains. Usually there is no shaking chill, but chilliness is very common. Headache is apt to be most distressing, at first being occipital in nature and later frontal. This is apt to be one of the most prominent features of the disease. Cough in most cases is nonproductive, but a few patients will bring up copious amounts of a thick, tenacious, whitish sputum. Pleuritic pain is usually absent. Perspiration is often quite profuse. Gastrointestinal symptoms, nausea and vomiting are often present early in the disease. Epistaxis is believed to occur in about 25 per cent of the cases.

Physical Findings—The temperature usually runs between 102 and 105 F and fluctuates from day to day. The pulse rate varies between 80 and 100, the increase being not at all in proportion to the rise in temperature. Actually there is a relative bradycardia. Respirations are usually normal or only slightly increased in rate. In a number of cases rose spots have been described.

Physical examination of the chest may result in any one of a number of findings. There may be no physical findings present at all, the x-rays being necessary to establish a diagnosis and usually revealing a small hilar or central pneumonic consolidation. Or there may be fine crepitant rales over the involved area with slight to moderate impairment of the percussion note. Finally there may be signs of frank consolidation. Usually the extent of pneumonic involvement will tend to parallel the severity of the infection, although this is not always the case. It is characteristic also that the physical findings will tend to migrate from time to time, traveling from one lobe to another.

Laboratory Data—The white blood cell count is normal or slightly elevated at the onset, with a tendency to develop a leukopenia later on in the disease. No characteristic change in the differential count has been observed. The sedimentation rate is elevated and tends to rise during the course of the disease. Sputum examination and culture reveal no organisms other than

those normally present in the pharynx. Blood cultures likewise are negative.

X-Ray Appearance—This varies considerably in some cases, depending on the severity and duration of the disease. Early there may be only an increase in one or both hilar shadows, the disease never progressing beyond this stage in many mild and moderately ill patients. On the other hand, the shadow may extend to become an extensive mottled patchy lesion involving one or more lobes. Finally, in many cases of severe illness there may be frank pneumonic consolidation. Serial roentgenograms will often establish the fact that the disease tends to be migratory in nature, jumping from one lobe to another or from the hilar area of the lung out into the periphery, advancing in one area while receding in another. Like the physical findings, the x-ray appearance frequently parallels the severity of the infection.

Course of the Disease—The duration of the febrile period varies from one to five weeks. The mild cases in which the illness does not appear acute usually last from one to two weeks. Those who are moderately and severely ill frequently have an illness lasting from two to five weeks. The temperature ranges between 101 and 105 F, varying from day to day. It is not uncommon for the temperature to return to normal for a day or two, only to relapse again. In addition to the two clinical types just described it is necessary to mention the very severe form, which is so often fatal. The febrile course in the severe type varies, ranging from one to five weeks, accompanied often by cyanosis and toxic cerebral symptoms in addition to the other features of the disease heretofore described. The mortality of this disease has been reported as high as 35 to 45 per cent. Apparently most of the cases which have been recognized have occurred in the group with severe infections in which one would expect a correspondingly high mortality. Also the severe type is usually seen in the older age group, who frequently have complicating chronic illnesses which cloud the picture.

Diagnosis—In addition to the history and clinical picture there are laboratory aids which are of value in confirming the diagnosis. Foremost of these is the isolation of the virus from the sputum of the patient. The sputum is most likely to yield the virus while the disease is still active. Isolation of the virus is accomplished in the following manner. At first a suspension of the infected material is inoculated intranasally into mice. After a period of four to eight days the mice are killed and their lungs examined for areas of consolidation. Finally, suspensions of the lungs of these mice are inoculated intracerebrally, intranasally and intraperitoneally into three groups of mice. Smears of the lungs and brains of mice dying in this group are examined for elementary bodies. It is also possible to isolate the virus from the livers and spleens of infected animals.

The blood is known to contain the virus until the fourth to the tenth day of illness, and it is possible to isolate the virus from it as well as from the sputum. The complement fixation test using an antigen prepared from the virus has been of inestimable value in early diagnosis of the disease. In many cases it is impossible to obtain any sputum and because of this the complement fixation test has been the means of confirming the diagnosis by most clinicians. This test is reliable, provided the patient has not been infected with the virus of lymphogranuloma venereum. Rake, Eaton and

Shaffer⁸ have shown that the viruses of lymphogranuloma venereum and meningopneumonitis psittacosis are antigenically related and that the serums of patients with lymphogranuloma venereum will fix complement with the psittacosis antigen.

Treatment—Until the present time there has been no specific treatment for ornithosis or psittacosis. Chemotherapeutic agents, specifically the sulfonamides, have had no influence on the course of the disease. This is likewise true in other cases of atypical pneumonia. Recent experimental evidence by Heilman and Herrell⁹ of the Mayo Clinic suggests that penicillin may prove to be of value in the therapy of ornithosis. These investigators inoculated 80 mice with the virus of ornithosis. They report that of 40 mice that were untreated 35 died, a mortality of 88 per cent. Of the 40 mice treated with penicillin only 2 died, a mortality of only 5 per cent. As this infection in human beings is not infrequently severe and often fatal, it is desirable that further work be done along these lines and that penicillin be given a fair trial in human infections of the virus of ornithosis. To meet this end it is desirable, and in fact necessary, that the diagnosis of ornithosis be established as soon as possible. Since the psittacosis antigen for

Fig 1—Case 1. A, tenth day and B, twenty-first day of illness.

complement fixation studies is not available commercially, it might be practical, in view of the cross reaction between the psittacosis virus and that of lymphogranuloma venereum, to employ the antigen prepared from the virus of lymphogranuloma venereum.

REPORT OF CASES

The following six sporadic cases of ornithosis were observed in the Philadelphia area during the past two years. In all 6 the diagnosis was confirmed by significant titers in the complement fixation test, which was possible only through the courtesy of Dr. K. F. Meyer of the George Williams Hooper Foundation at the University of California.

CASE 1 (figs 1, 2 and 3)—**History**—F. R., a white man aged 55, who was admitted to the hospital on Jan. 1, 1944 and discharged on February 10, first noticed the onset of general malaise and sore throat seventeen days prior to admission. Nine days before admission he had an abrupt onset of chills, fever, frontal headache, cough, nausea and vomiting, which persisted until entry into the hospital. Sulfadiazine had had no influence on the fever. On admission the patient perspired profusely and looked acutely ill. The temperature was 100.4 F, the pulse rate 78 and the respiratory rate 20. Examination of the chest

⁸ Rake G., Eaton M. D., and Shaffer M. F. Similarity and Possible Relationship Among Viruses of Meningopneumonitis, Lymphogranuloma Venereum and Psittacosis. *Proc. Soc. Exper. Biol. & Med.* 48: 528 (Nov.) 1941.

⁹ Heilman T. R. and Herrell W. E. Penicillin in the Treatment of Experimental Ornithosis. *Proc. Staff Meet., Mayo Clin.* 19: 57 (Feb. 9) 1944.

showed dullness, increased tactile fremitus and medium moist rales over the right lower lobe

Laboratory Data—White blood cells numbered 12,000, polymorphonuclears 82 per cent lymphocytes 18 per cent Blood and sputum cultures were negative X-ray examination revealed a pneumonic consolidation involving the posterior portion of the right lower lobe

Fig 2—Case 1 A twenty sixth day and B thirty eighth day of illness (afebrile three days)

Course—Fever persisted twenty-four days with daily fluctuations in temperature ranging from 98.5 to 103.2 F. Profuse perspiration accompanied the daily elevations in temperature. By the end of the first week the pneumonic process had spread to involve the right upper lobe. Cold agglutinin studies were done several days after admission and found to be negative. On the twenty-fifth hospital day the temperature fell abruptly to normal.

Epidemiology—The patient was the owner of a small pigeon flock. Two weeks before the onset of his illness 1 of the pigeons had died and he had performed a layman's autopsy. The cause of death of the pigeon is not known. Serum obtained on the twenty-fourth day of his illness had a psittacosis complement fixation titer of 4+, 1:512.

CASE 2 (figs 4 and 5)—**History**—H. S., a white man aged 47, admitted to the hospital on Feb 2, 1944 and discharged on March 9, had a sudden onset of chills fever, aching pain in the chest and a nonproductive cough one week before admission, all of which had persisted. The past history showed typhoid in 1913. On admission the patient did not look acutely or chronically ill. The temperature was 103.4 F, pulse rate 98, respiratory rate 28. Blood pressure was 138/90. Examination of the chest was negative except for a few crepitant rales heard posteriorly over the right lower lobe. There were no changes on percussion or tactile fremitus.

Laboratory Data—White blood cells numbered 7,300, polymorphonuclears 81 per cent lymphocytes 19 per cent. Blood culture was negative. X-ray examination of the chest showed a small area of hilar consolidation present in the right cardiophrenic angle.

Course—Fever persisted for fourteen days fluctuating between 101 and 104.4 F daily. On the fourteenth day the temperature began to fall by lysis and was normal on the nineteenth hospital day. Sulfamerazine was used with no effect. Physical examination of the chest after admission was always negative. On the fourth hospital day cold agglutinins were done and found to be negative.

Epidemiology—There was no history of direct pigeon contact in this case. However, there is quite a large flock of pigeons in the neighborhood surrounding his home and he states that the birds frequently rest on his window sills. Serum obtained on the fourth hospital day had a psittacosis complement fixation titer of 4+, 1:128.

CASE 3—History—M. A., a white man aged 40 was admitted to the hospital on March 13, 1942 complaining of fever, chills, malaise, excruciating frontal headache, joint pains and cough of five days duration. On admission the patient looked acutely ill. The temperature was 103.6 F, pulse rate 100, respiratory rate 24. Blood pressure was 110/80. Examination of the chest

showed slight dullness and diminution of breath sounds over the right lower lobe. No rales were present. There was also some tenderness over the right upper rectus muscle.

Laboratory Data—White blood cells numbered 4,600, polymorphonuclears 78 per cent, lymphocytes 22 per cent. Blood culture was negative. X-ray examination of the chest showed fine, soft, diffuse mottling throughout both lung fields, with a slight increase in the size and density of both hilar shadows.

Course—Fever persisted for seven days, fluctuating daily between 101 and 105 F. After four days sulfathiazole was discontinued because of a drug rash. On the seventh day the temperature fell abruptly to normal, where it remained. Severe frontal headache was the most prominent feature of the patient's hospital stay.

Epidemiology—This patient had played with a pair of love birds three days before admission, but at that time he had already been sick with fever for two days. It was discovered that the patient's home adjoined a large park which contained many pigeons and that many of these birds nest on his home. However, he had not fed or handled any birds. Serum taken from the patient on April 29 had a psittacosis complement fixation titer of 4+, 1:64.

CASE 4—History—G. P., a white woman aged 25, a housewife, was admitted to the hospital on July 20, 1942 complaining of chills, fever, malaise and cough of three days' duration. On admission the patient was not acutely ill but complained of a distressing cough. The temperature was 103.3 F, pulse rate 104, respiratory rate 24. Blood pressure was 105/65. Physical examination of the chest was not remarkable outside of some dullness and diminished tactile fremitus over the right scapular region. No rales were present.

Laboratory Data—White blood cells numbered 6,800, polymorphonuclears 83 per cent, lymphocytes 17 per cent. Blood culture was negative. X-ray examination of the chest showed mottled clouding and peribronchial infiltration extending down ward and laterally from the right hilus to the periphery in the right middle and lower lobes.

Course—Fever persisted eighteen days, fluctuating daily between 100 and 103 F. Sulfadiazine was given for four days

Fig 3—Course in case 1

and stopped when there was no response. Several small transfusions seemed to have a beneficial effect. On the fourteenth day of illness the temperature began to fall by lysis, and it was normal on the eighteenth hospital day.

Epidemiology—This patient denied any direct contact with birds. However, she stated that pigeons continually roost on her window sills, but she denied having handled or fed them. Serum taken from the patient had a diagnostic titer in the psittacosis complement fixation test of 4+, 1:16.

CASE 5—History—D A, a white woman aged 44 was admitted to the hospital on Aug 8 1942 complaining of chills, fever, headache and profuse perspiration of twelve days' duration Sulfonamide therapy had had no effect on the illness On admission the patient looked acutely ill and was complaining chiefly of severe frontal headache Examination of the chest showed only a few fine crepitant rales at the left base

Fig 4—Case 2 A eighth day of illness B eighteenth day of illness

Laboratory Data—White blood cells numbered 11,000, polymorphonuclears 75 per cent, lymphocytes 23 per cent, eosinophils 2 per cent Blood culture was negative X-ray examination of the chest showed accentuation and feathering of the broncho-vascular markings, extending particularly into the lower lobes of both lungs, with similar but less definite changes in the upper lobe

Course—Fever persisted for sixteen days with daily fluctuation from 100 to 102 F On the sixteenth hospital day the temperature fell abruptly to normal There was no response to sulfathiazole

Epidemiology—No history of contact with pigeons or birds of any kind could be obtained The patient however, lived within several blocks of patient 3 and likewise had many pigeons about the roof and premises Serum taken from the patient had a diagnostic titer of 4+, 1:128 in the psittacosis complement fixation test

CASE 6—History—G P, a white man aged 68 noticed the abrupt onset of chills, fever, severe frontal headache nausea and vomiting about Nov 1, 1943 Despite this he continued working and one week later collapsed became delirious and was put to bed On examination he appeared acutely ill The temperature was 104 F, pulse rate 90, respiratory rate 24 Examination of the chest revealed slight dullness and fine crepitant rales at the right base On the seventh day the temperature began gradually to fall by 1.5° and reached normal by the thirteenth day of illness He was extremely toxic and acutely ill throughout the extent of his illness

Epidemiology—The patient keeps a flock of about 300 pigeons and is in daily contact with them The complement fixation reaction for psittacosis was 4+, 1:16

COMMENT

It is perhaps worthy of note that in 4 of the 6 cases observed there was no history of direct contact with pigeons or any other birds However, in all 4 cases there were pigeon flocks in the immediate vicinities of their homes This is not at all unusual, as it is known that infection may take place through the inhalation of infected droppings blown about as dust Because of the large potential reservoir of infection present in the many pigeon flocks throughout the country, it is important that the extent of ornithosis among pigeons be determined Meyer and his collaborators³ made a survey of pigeon lofts in various areas throughout the country and found that a very high percentage of the flocks studied had significant titers in the psittacosis complement fixation test Meyer states that 40 to 50

per cent infection of pigeons with ornithosis is of universal occurrence Hoping to obtain further information on the extent of infection among pigeon flocks in this area, we captured 14 pigeons with the cooperation of the Philadelphia Department of Health Examination of their serums revealed diagnostic complement fixation titers in 6 pigeons, 42 per cent of the number examined However, a positive complement fixation titer does not necessarily mean active infection but may mean latent, inactive or subclinical infection Also birds with negative titers may harbor the active virus in their livers or spleens

The mortality of psittacosis has been reported as high as 40 per cent Meikeljohn Beck and Eaton⁷ reported a fatal outcome in 4 of 10 cases They also noticed a high degree of secondary infection in that 3 nurses who attended the original 2 patients contracted the infection We have observed no such secondary infection It is likely that a mortality of 40 per cent is too high for ornithosis and that attention is focused on those cases in which the illness is very severe or prolonged and that perhaps many milder cases of shorter duration pass by unnoticed

In February 1943 Peterson, Ham and Finland¹⁰ observed the presence of a reversible cold autohemagglutinin occurring in 2 patients who developed acute hemolytic anemia during the course of an atypical pneumonia Further study showed that cold agglutinins were present in significant titers in most cases of atypical pneumonia The titers obtained ranged from 1:10 to 1:10,000 A review of the literature indicated that cold agglutinins are rarely if ever present in bacterial pneumonias The suggestion was proposed that this test might be of value in confirming the diagnosis of an atypical pneumonia as distinct from a bacterial pneumonia, as at the present time the nature of the etiologic

Fig 5—Course in case 2

agent of the atypical pneumonia in most cases has not been definitely established Meikeljohn¹¹ confirmed the observations of Finland and his co-workers The observation was made that the rise in titer of cold agglutinins begins on the eighth to the tenth day, reaches

¹⁰ Peterson O L Ham T H and Finland M Cold Agglutinins in Primary Atypical Pneumonias Science 97 167 (Feb 12) 1943

¹¹ Meikeljohn G The Cold Agglutinin Test in the Diagnosis of Primary Atypical Pneumonia Proc Soc Exper Biol & Med 54 181 (Nov.) 1943

a peak anywhere from the twelfth to the twenty-fifth day and falls off rapidly after the thirtieth day. During the past several months cold agglutinins have been investigated at the Abington Memorial Hospital.¹² The results in 40 cases of pneumonia, 20 being atypical and 20 bacterial (chiefly pneumococcal), are summarized in the accompanying table.

Among the bacterial pneumonias cold agglutinins were significantly absent and only 1 case had a questionable titer of 1:20. In the group of atypical pneumonias cold agglutinins were absent in 3 cases and present in significant titers in the remainder. Two of the 3 negative cases in the atypical group were cases of ornithosis which have been reported in this article. Cold agglutinins in these cases were determined on the twentieth and fifteenth days of their febrile periods when the cold agglutinins, if present, should have been at the peak of their titer. Meikeljohn¹¹ observed 2 cases of psittacosis in which cold agglutinins were performed. In 1 the titer was less than 10 and, in the other, titers of 10, 10, 20 and 10 were present on the sixth, tenth, fifteenth and thirtieth days of the disease respectively. They considered values of 20 and over as probably being significant. Whether or not these values of cold agglutinins in psittacosis will have any significance must await further studies along these lines. The value of cold agglutinins is as a means of confirming the diagnosis of an atypical pneumonia till the etiologic

Cold Agglutinins in Atypical Pneumonia

Bacterial pneumonias (pneumococcus)	70	0	1	0	0	0	0	0	0	0

agent can be better identified. Its use is limited as an early diagnostic aid, since a significant titer is not usually obtained until the end of the second week, at which time the patient is well on the road to recovery.

SUMMARY AND CONCLUSIONS

1 In 6 sporadic cases of ornithosis the diagnosis was confirmed by means of the complement fixation test.

2 A history of direct contact was obtained in 2 of the reported cases. In the others there was no history of any direct contact, but daily exposure to pigeons occurred in the immediate vicinity of the homes. It is known that infection may occur through the inhalation of the infected excreta of pigeons blown about as dust.

3 Examination of the serums of 14 pigeons captured in Philadelphia showed diagnostic complement fixation titers to ornithosis in 6 pigeons, 42 per cent of the total examined. Infection of pigeons with ornithosis averaging 40 to 50 per cent is thought to be of universal occurrence.

4 The absence of any fatalities among the 6 reported cases clouds the fact that the mortality is frequently reported as high as 40 per cent. Apparently many mild cases pass unrecognized.

5 Observations were made on the presence of cold agglutinins in atypical pneumonia. Two cases of ornithosis were examined for cold agglutinins and both found to be negative. The significance of this awaits further study.

6 Recent experimental work by Heilman and Herrell⁹ of the Mayo Clinic suggests that penicillin may prove of value in the treatment of ornithosis.

7 In view of the high percentage of infection among the pigeon population in the United States, and since countless individuals are daily exposed to this potential reservoir of infection, it is probable that the virus of ornithosis may be responsible for many sporadic cases of primary atypical pneumonia which pass unrecognized.

Clinical Notes, Suggestions and New Instruments

THE USE OF THEOPHYLLINE ETHYLENEDIAMINE (AMINO-PHYLLINE) FOR THE RELIEF OF BILIARY COLIC A PRELIMINARY REPORT

ARTHUR GLADSTONE, M.D. AND LOUIS GOODMAN, M.D.
BURLINGTON, VT

Our purpose in this communication is to call attention to the use of theophylline ethylenediamine for the relief of biliary colic. For many years it has been known that the xanthines are capable of relaxing certain smooth muscles. Thus, theophylline has been employed for symptomatic relief of patients with angina pectoris and bronchial asthma.¹ The antispasmodic action of theophylline, however, is not manifested to any great extent on the gastrointestinal tract. Nevertheless it has been shown by Butsch, McGowan and Walters² that theophylline ethylenediamine is effective in overcoming spasm of the biliary tract produced in man by the injection of morphine, dihydromorphine hydrochloride (dilaudid) or codeine. It is well known that the phenanthrene alkaloids of opium produce spasm of smooth muscles of hollow viscera. Morphine relieves pain due to such spasm only by virtue of its analgesic action on the central nervous system. Locally, the mechanism for the production of pain is augmented. Butsch and his associates² obtained kymographic tracings in man by means of a water manometer connected to a T tube inserted into the common bile duct for prolonged biliary drainage after exploratory operation. The subcutaneous injection of morphine, dihydromorphine hydrochloride or codeine in the usual therapeutic doses quickly caused an increase in intrabiliary pressure which persisted for two hours or more and which was at times associated with typical biliary colic. Atropine and papaverine were not effective in relieving this morphine induced spasm of the biliary tract. In contrast, amyl nitrite by inhalation and glyceryl trinitrate sublingually decreased the elevated intrabiliary pressure and concomitantly relieved pain. Theophylline ethylenediamine (0.24 Gm.) given intravenously rapidly lowered intrabiliary pressure to normal, although the relaxation was temporary, owing to the continued action of morphine. It occurred to us, therefore, that theophylline ethylenediamine might be a useful therapeutic agent for the symptomatic relief of biliary colic. Indeed this suggestion has previously been recorded by one of us.¹

We have thus far had occasion to observe the effects of theophylline ethylenediamine injected intravenously in 8 cases of acute biliary colic. Pain was usually promptly relieved. No untoward effects were observed. A brief presentation of representative cases follows.

Mrs. L. G., aged 35, experienced indigestion and upper abdominal discomfort during pregnancy in March 1942. Cholecystography in March 1944 revealed poor function and multiple small calculi. In May 1944 there occurred an acute attack of right upper quadrant abdominal pain, which began suddenly and became progressively worse. Theophylline ethylenediamine (0.5 Gm. in 20 cc. of aqueous solution) was injected intravenously over a period of four minutes. Relief from pain occurred before injection was completed. No untoward effects were experienced.

From the Departments of Surgery and Pharmacology, University of Vermont College of Medicine.

Gynec. & Obst. 63: 451-456 (Oct.) 1936. Walters, W. McGowan, J. M., Butsch, W. L. and Knepper, P. A. *Pathological Physiology of Common Bile Duct: Its Relation to Biliary Colic*. J. A. M. A. 109: 1591-1597 (Nov. 13) 1937.

Mrs J L, aged 28, an obese mother of 4 children, had clinical evidence of gallbladder disease since her second pregnancy, four years before. In the second month of her fifth pregnancy there occurred an attack of fairly severe right subcostal pain, which was somewhat intermittent in character. The family physician had given medication orally four hours before without relief. Theophylline ethylenediamine (0.5 Gm) was injected slowly intravenously. The patient quickly experienced almost complete relief and slept fairly well during the night but still had some slight, dull aching discomfort in the upper abdomen the next morning. No untoward effects were observed.

Mrs O W, aged 51, had two previous hospital admissions for upper abdominal pain and a diagnosis of cholecystitis was made. In March 1944 she was admitted with severe abdominal pain, referred to the right shoulder and back and aggravated by breathing. The abdomen was considerably distended. She had had two injections of morphine without relief. Theophylline ethylenediamine (0.5 Gm) was injected very slowly intravenously. The patient, who was highly nervous, began to complain of "heart pounding." The blood pressure, which was 104/74 before injection, was 118/74 two minutes after injection. The pulse rate increased from 84 to 100 per minute. The cardiac rhythm was normal. Fifteen minutes after injection the patient admitted complete relief of abdominal pain.

Mrs I G, aged 35, had a cholecystectomy performed in December 1942 for acute cholecystitis. The common duct was not explored. In March 1944 she experienced very severe colicky pain in the right upper abdominal quadrant. Morphine, atropine and phenobarbital were administered by her physician over a period of twenty-four hours with little relief. On admission to the hospital her pain was severe. The icterus index was 35. She was given 0.5 Gm of theophylline ethylenediamine very slowly intravenously. During the injection a sensation of warmth accompanied by slight transitory nausea was experienced. No other untoward effects were noted. Almost immediately after completion of the injection the pain was altered in character and was entirely relieved in ten minutes. Sleep was possible for the first time in many hours. Six weeks later the patient complained of a dull, less severe pain in the same region and feared a recurrence of the severe pain. Only 0.25 Gm of theophylline ethylenediamine was given on this occasion. Complete relief again occurred in eight to ten minutes.

As a result of the experience recorded, it was thought that the use of theophylline might be helpful in obtaining specimens of gallbladder bile during duodenal intubation. The following case illustrates such a use.

Mrs H O, aged 45, with a chief complaint of chronic indigestion, was having a duodenal intubation for the purpose of obtaining specimens of gallbladder bile. None was obtained by the usual methods (instillation of magnesium sulfate solution olive oil, peptone). Theophylline ethylenediamine (0.5 Gm) was injected slowly intravenously. Immediately after completion of the injection an active flow of dark, concentrated bile was obtained. No untoward effects were experienced.

COMMENT

The use of theophylline ethylenediamine intravenously is not new, and physicians employing it for patients with bronchial asthma, paroxysmal nocturnal dyspnea, Cheyne-Stokes respiration and so on are well acquainted with the technique and necessary precautions for its intravenous use. The most important precaution is that the injection be made slowly in order to prevent the fall in blood pressure which may occur on rapid intravenous administration of xanthines.³

A fairly diligent search of the literature has yielded but scant reference to the clinical use of theophylline in biliary colic. Means and Delor⁴ record having had "excellent results with 4 grains of aminophyllin intravenously or the inhalation of a perl of amyl nitrite," but no details are given. They also mention the successful oral use of aminophylline (0.1 Gm) and theobromine with sodium salicylate (0.5 Gm) four to six times daily. Means and Delor refer to the use by Musser of theo-

phylline ethylenediamine in a series of cases without side effects but no reference is given and we have been unable to locate it.

Our experience would seem to warrant further clinical trial of theophylline as an antispasmodic for the biliary tract. The choice of drugs for this purpose is limited. Atropine and papaverine are usually not effective. The nitrites may provide some measure of relief, and occasionally the response to glyceryl trinitrate is dramatic. The synthetic atropine substitutes may at times be useful and have a more selective action than atropine. Morphine, the traditional drug employed in acute biliary colic, may fail to relieve pain and in certain cases may aggravate the pain. This also holds true for codeine and dihydromorphine hydrochloride. As stated, morphine and its congeners actually increase the degree of smooth muscle spasm and thus augment the mechanism for production of pain. If relief occurs, it is due entirely to a central analgesic action of morphine. Iso-meprecrine should prove more valuable than morphine for symptomatic therapy of pain due to smooth muscle spasm because it not only is a potent central analgesic but also has a local antispasmodic action.

Theophylline ethylenediamine has given relief to patients on whom morphine was without effect. Its action is usually prompt, and the full measure of relief to be expected occurs in two to twenty minutes. There would appear to be no reason why the intravenous injection of theophylline ethylenediamine should not be repeated in two or three hours, if biliary pain recurs. We have not had occasion to use it by mouth or by rectal suppository, nor have we tried salts of theobromine.

The results recorded here do not allow designation of the exact mechanism of action of theophylline in the relief of biliary colic, but it would seem likely that the antispasmodic action is operative. This is probably exerted directly on the musculature of the biliary tract and perhaps also on the gallbladder, rather than on the duodenum. The effect of xanthines on the tone and motility of the human intestine is not impressive. However, it is possible that theophylline may also cause relaxation of the sphincter of Oddi, as suggested by the case cited in which the obtaining of bile specimens transduodenally was facilitated.

SUMMARY

Our purpose in this report is to call attention to a useful but neglected application of the selective antispasmodic action of theophylline. The intravenous injection of 0.25 to 0.5 Gm of theophylline ethylenediamine has given satisfactory and often complete relief of pain in acute biliary colic. The drug may succeed when other measures fail. Untoward responses were not encountered in the small series of cases reported here. Theophylline may also prove useful in obtaining specimens of bile by means of duodenal intubation when other agents are without effect.

Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement
AUSTIN SMITH, M.D., Secretary

BENZESTROL, A NONPROPRIETARY DESIGNATION

The Council has accepted for inclusion in New and Non-official Remedies a synthetic estrogenic substance known chemically as 2,4-di(p-hydroxyphenyl)-3-ethyl hexane. The Council has recognized the right of Schieffelin & Company to a proprietary name, and their product has been accepted under the designation Octofollin (THE JOURNAL, March 3, 1944, p 647). The firm has since informed the Council that it will not use the name Octofollin but will market its product under the non-proprietary name Benzeestrol.

Other firms will be licensed to supply the drug, and, to forestall confusion in the future, the Council has given consideration to a nonproprietary name for the drug and voted to recognize Benzeestrol as the nonproprietary term for 2,4-di(p-hydroxyphenyl)-3-ethyl hexane.

HEALTH EDUCATION IN BOSTON SCHOOLS

From Boston, renowned as a center of culture, comes the disturbing news that health education in the Boston schools is at a low ebb and health practices in these same schools leave much to be desired. These are the claims made by the Strayer School Survey.¹

Among the criticisms the following are significant. There is no excuse for teaching in the third grade the same health material presented in the first grade. Health teaching in the Boston schools is characterized as "halting, limited, superficial and indifferent" and the Strayer surveyors find it "difficult to understand the policy that started health instruction in the schools and have made no provision for textbooks for the pupils." Many of the health lessons are characterized as writing exercises rather than health lessons. "The teacher dictates from a book and the children write what is dictated. With this sort of thing going on it is not strange that public education is sharply criticized in its methods."

Health examinations are made in about one minute's time per pupil. The Strayer report suggests eliminating the requirement that all pupils be examined every year and that more thorough examinations at longer intervals be substituted with special attention given to all new pupils, those competing in sports and those referred for special attention by teachers or nurses. Special attention should be given to pupils returning to school after illness.

Not only is health instruction and health examination practice unsatisfactory, but first aid and health rooms in some schools are found inadequate. The school plant and its operation also are criticized.

The school plant should be the place that exemplifies all the best that we know in the field of health. This is not the case in Boston. Children in the Boston schools may study the value

of fresh air and the importance of good ventilation. But in one school there were double windows still on in May. In another the windows cannot be opened because of broken window cords or chains.

In still another there are so many plants on the window sills that the windows are not opened for fear of chilling the plants or injuring them. Many of the school assembly halls are poorly ventilated. One of them is grossly overheated regularly. The children have their eyes tested for vision and are sent to the oculist, but in some of the old buildings the light is very faulty and artificial lighting is very inadequate.

In certain schools children are not allowed to go to the toilet or even get a drink without the teacher's permission. In some bubble fountains the water is so hot and bad tasting that children go without it. Washing of hands is discouraged because of lack of facilities. Not one container for soiled paper towels was found. In some schools toilet rooms were dirty and uncared for. Children study nutrition, but the lunchrooms offer menus that are largely carbohydrates.

Recalling that Boston was a pioneer in health education, physical education and recreation, the Survey reports "these three areas, once so bravely pioneered, have not been maintained at the high level that might be expected."

The story about Boston and its schools is significant because in place of Boston one might put the names of a large number of American cities. This condition, which in Boston is at least being studied as a first step toward providing remedies, exists in too many cities, large and small where it is not even recognized. There are of course American communities, both large and small, in which school health work is done on a high level, where school health authorities are constantly on the alert and where health departments and the schools cooperate effectively for the health of school children. School health conditions in the three principal fields, namely health instruction, health examination and guidance and healthful living practice, range from the very best to the very worst according to locality. However, on a nationwide basis school health service is probably the spottiest and least effective branch of standard recognized public health procedure.

The medical profession and the educational profession are alert to the situation. For thirty-three years a joint committee of the National Education Association and the American Medical Association has been active in the field of health problems in education. Its report "Health Education"² is a standard textbook in this field today, as it was a pioneer in its first edition in 1925. The American Association of School Administrators in

¹ Strayer School Survey by Louis M. Lyons. Boston Daily Globe, Nov. 13, 1944.

² Health Education. Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, ed. 3, 1941.

its 1942 Yearbook³ recognized the importance of health in the schools and addressed the book directly to school administrators, recognizing in them the key to improvement in health conditions in the schools. Four of the scientific sections of the American Medical Association, cooperating with the Joint Committee and with four sections of the American Public Health Association and with the Association for Health Physical Education and Recreation, have issued a brief statement on suggested school health policies⁴ which has been widely used by school administrators and in teachers' colleges. There is substantial agreement between the two great professions, medical and educational, concerned with health problems in education. Principles have been recognized and standard practices are well defined. Local communities need to apply these principles. Such studies as the Strayer Survey in Boston and the publicity given to them are constructive stimuli to improvement in the school health field. If the nation is going to have the physical fitness which military authorities, physicians and educators now demand, the basis for such fitness must be the good health of our young people. These young people are now being delivered to our schools in a better state of health than ever before. The schools must face the responsibility of delivering them back to the community at the end of their educational experience in a state of health better, if possible, than at the beginning but certainly no worse. Hundreds of American cities could profitably follow Boston's example, bringing to light and publicizing their own weaknesses and then taking steps to correct them.

DEMOBILIZATION AND DOCTORS

The ever tightening encirclement of Germany and the increased flow of men and supplies to the Allied Armies indicate ultimate victory in Europe in the not too distant future. Germany has not, however, been defeated, and military leaders assert that bitter fighting is still ahead. However, assurance has been given that victory will be ours in the European war. Without minimizing the efforts that must be given by all to attain an early defeat of Germany, the problems of winning the war against the Japanese must be considered also.

Armies and navies are organized and equipped to achieve specific objectives. They are no longer rigidly constituted bodies conforming to traditional tables of organization, instead, they are built now to accomplish definite aims. Successful operations against the Japanese will no doubt require a striking force different

from that used against the Germans. After the occupation of Germany a reorganization of the Army may be anticipated to make it the most effective striking power against the Japanese. The Navy has already transferred most of its amphibious forces from the Atlantic to the Pacific. Experience in the Pacific shows that jungle warfare requires tough, young, aggressive soldiers. The same qualifications are needed for medical officers, who must follow troops closely to render the most effective medical service. Discussions in the halls of Congress intimate that there will be a reduction in the size of the Army after the defeat of Germany but that the Navy will continue to expand until it reaches its full authorized strength.

The War Department has recently published a series of directives, called "Readjustment Regulations," outlining the mechanism by which men will be released from service. Soldiers will be released on a point system whereby credits are given for length of service overseas service, active participation in campaigns and battles, decorations and awards and dependents. Administrative details and techniques of operations are being perfected.

Medical officers occupy a unique position in the plans for partial demobilization of the Army after it conquers Germany. There are special considerations that must be given to a profession that has more than one third of its active members in the armed forces. A partial redistribution of physicians between the civilian population and the armed forces must be effected to equalize the tasks of physicians of a nation at war.

Definite plans for the reallocation of physicians between the services and civilian communities in Great Britain have been announced by a special committee known as the Demobilization Committee of the Central Medical War Committee. At the request of the Ministry of Health the Demobilization Committee made a special study of the situation and suggested the selection of two groups of men for return to civilian life. Class A, the larger group, will be chosen according to age and length of service.

Within class A there will be special priority for men of 50 years of age and over, who will be released before other men if they so wish. Otherwise, men in class A will be released by release groups determined by a combination of age and length of war service on the basis that two months of service are equivalent to one additional year of age. For example, a man of 22 with four years' service will be in the same release group as a man of 40 with one year's service.

The release of men in class A will begin as soon as practicable after the defeat of Germany, but there will necessarily be a pause to enable the services to identify the men who are to be released first and to arrange for the return to this country of those who are overseas. The number of releases in class A will depend on the reduction that is found to be possible in the strength of the forces and also on the number of new recruits called up.

³ Health in Schools Yearbook, American Association of School Administrators.

⁴ Suggested School Health Policies, American Medical Association. Single copies free when requested on official letterhead.

To assist in resettlement, men in class A will receive on release eight weeks leave with full pay and certain allowances, and additional leave and pay will be given in respect of foreign service. When the period of leave has expired these men will be placed in a special class of Reserve, from which they would be recalled only in an extreme emergency.

A smaller group, class B, will be used to supplement the labor force needed for construction after the war. Men will be transferred into class B on the basis of special occupational qualifications, age and length of service. Since such men will leave the service earlier than their turn, they will not be entitled to the same benefits as those in class A but will be held in the Reserve and be liable for further military duty. All transfers of medical officers from the services to class B will clear through the Central Medical War Committee. The release of men from class A will aid effectively in the hard pressed civilian medical services. In England there is a national service act that facilitates the solution of problems concerned in medical care.

The time is not too soon for serious thought on the many faceted problems of demobilization of doctors from the armed forces. Some of these problems are now being considered by the Committee on Postwar Medical Services.

STANDARDS OF PHYSICAL FITNESS

What is physical fitness? Is it the ability to resist fatigue? Is it longevity or is it muscular strength? Or is it a combination of these and perhaps other ingredients? Many discussions of physical fitness neglect to define accurately the standards and aims of physical fitness programs. Physical fitness is neither a fixed standard nor an average but rather an objective. A man of 20 to be physically fit should be able, perhaps, to carry a 40 pound pack 20 miles in eight hours, at the age of 14 or at 50 the same man probably would not be able to perform this task, and yet he could be considered physically fit. A farmer of 45 should have a different standard of physical effectiveness than a politician of the same age. The standards of physical fitness are different for men and for women. As a group, women have less muscular strength and endurance than men. They stand pain better and live longer on the average. Thus age, occupation and sex are important elements which must be considered in setting any kind of ideal standard. Other aspects of a standard offer fewer difficulties. Certainly a person with a hernia, carious teeth or poor vision, for example, cannot be considered physically fit, regardless of age, occupation or sex. The elimination of preventable or remediable defects is a step toward physical fitness.

Certain criteria of physical fitness may be eliminated in relation to particular occupations. The ability to run a mile, lift a heavy weight or perform similar feats of muscular strength or endurance may be useful only

for those who are required to do these things because of military or occupational necessity. At certain ages, of course, physical normality should include the potentiality of being trained into a degree of "physical fitness" and performing thereafter certain activities which had been impossible in the pretraining period.

The development of methods for the objective determination of standards of physical fitness at various ages for different types of occupation and for the two sexes is badly needed. To date the simplest tests of fitness are cardiovascular and respiratory, a third type of test evaluates the ability to resist fatigue in response to sensory stimuli. These measurements are still deficient in certain respects, however, and much further work remains to be done. Until there is more agreement on acceptable testing methods it will be difficult to adopt standards of physical fitness.

There is a recognizable difference between the ideal and a practical physical fitness program. Not all young men can develop equal degrees of muscular strength or endurance. Some who cannot attain perfection measured by those criteria may demonstrate by their greater longevity a higher degree of fitness, at least in that respect, than those who more closely approach the ideally developed physical specimens. Discrimination in these matters is essential, all physical "standards" should include recognition of the fact that deviations from them do not necessarily condemn the substandard person to a life of inactivity, to poor health or to early death.

The psychologic aspects of the physical fitness programs must not be neglected. Some people who do *not measure up to any standards likely to be adopted* may consider themselves physical wrecks, this may have serious psychologic repercussions. To counteract this possible hazard it is merely necessary to point out that human history contains the records of many persons who have achieved distinction, fame and fortune in the face of physical defects which would disqualify them on the basis of any conceivably acceptable standards. Indeed, the contemporary scene likewise presents many figures who have been notably successful in the face of severe physical defects.

To increase the general average of physical fitness is the purpose of the current campaign. The elimination of inherited defects is not commonly included in the physical fitness program, but its part in the problem should be recognized. Influencing the environment is the major avenue of approach. The environment may affect the physical condition by means of diet, disease, working conditions, presence of remediable defects and recreation, including physical exercise. The latter alone will alter the physical condition to a limited extent only. Such factors as those mentioned must be attacked if the highly desirable objective of improving the general physical condition of the American people is to be achieved with maximum success.

GLUTAMINE

Glutamine in the blood, as previously pointed out in these columns,¹ is the source of the ammonia in the urine. The functional importance of ammonia as the endogenous base makes this fact especially significant in metabolism. Glutamine, an acid amide, is a constituent of the protein molecule. It may occur free in certain tissues, as indicated by its discovery in horse meat extract in a study² which, furthermore, proved its indispensability for the growth of the hemolytic *streptococcus*.

Glutamine is also present in body fluids. In 1942 Hamilton³ pointed out that in picric acid filtrates of human and canine plasma there is present an organic compound containing nitrogen which behaves strikingly like glutamine when heated at an acid reaction. Shortly thereafter another report⁴ called attention to a glutamine-like substance in the protein free filtrate of plasma and serum of man and rabbit in a concentration of 5 to 10 mg per hundred cubic centimeters. These observations are given added weight by the perfection of an analytic method depending on the highly specific enzyme glutaminase prepared from dog kidney. Using this procedure, Archibald⁵ has found 6 to 10 mg of glutamine per hundred cubic centimeters in normal human plasma and has shown that the white and yolk of the egg contain this compound, the concentration in the latter decreasing during incubation. There seems little doubt, in the light of the foregoing observations, that glutamine is a normal constituent of the blood.

Glutamine has been recognized as a usual component of the cells of many plants for more than half a century. It can be prepared readily from the common beet,⁶ and the concentration in plants has been shown to respond readily to nitrogenous fertilizers.⁷ In plants glutamine is believed⁸ to represent an intermediate stage in the transfer of nitrogen from the storage protein of the seed to the tissue protein of the growing parts, and its concentration is influenced by the respiratory activity of the plant.

Already the observation⁹ has been made that carbohydrate metabolism is related to the presence of glutamine, administration either of insulin or of glucose decreases the amount of glutamine in the blood. More

data are needed before a complete picture of the metabolic function of glutamine can be suggested, there seems little doubt, however, that some current uncertainties with respect to intermediary metabolism will be removed when this is done.

Current Comment

VISCERAL REACTIONS TO ANOXIA

The occurrence of myocardial necrosis and calcification in dogs subjected to tourniquet shock¹ or histamine shock² attracts attention once more to the visceral reactions following anoxic episodes of varying duration affecting the heart, aorta, brain, testes and bone marrow. Similar degeneration, necrosis and fibrosis of the myocardium have been observed in man and in animals after poisoning with epinephrine, nicotine, digitalis glycosides, parathyroid injection, vitamin D, nitrites, carbon monoxide, carbon disulfide and reduced oxygen pressure and also after excessive physical labor. The lytic necrosis with cyst formation in the media of the ascending aorta of man after burn shock, of dogs after histamine shock and of rabbits following the injection of epinephrine are evidently also of anoxic genesis. Focal softenings and gliosis of the brain often located in the basal ganglions and giving rise to parkinsonism have been observed in man and animals after poisoning with carbon monoxide, carbon disulfide, cyanide, nitrites, manganese, mercury, lead, digitalis glycosides and pitressin and after exposure to reduced oxygen pressure. The spermatogenic epithelium of the testis appears to be similarly sensitive to anoxia. Degeneration of this tissue was seen after prolonged exposure to reduced oxygen pressure (chronic mountain sickness) and after poisoning by carbon monoxide and disulfide, nitrites, mercury, manganese, nicotine and lead. After a transitory period of increased libido there follows in general loss of libido and sterility, which is reversible in the early stages but may ultimately become permanent. These regressive visceral reactions to anoxia contrast with the hyperplastic response of the marrow to this condition resulting in erythrocytosis. Anoxic erythrocytosis develops under the influence of reduced oxygen pressure (mountain sickness), after chronic exposures to carbon monoxide, nitrite and cyanide, and after manganese, epinephrine, amphetamine, ephedrine, posterior pituitary injection and lead, and also on insufficient oxygenation of the blood due to a reduced pulmonary circulation from various causes. Anoxic erythrocytosis, however, occurs only when the impairment of the oxygen metabolism is mild. Severe degrees of anoxia produce atrophic changes in the marrow resulting in anemia. From these data apparently those organs mainly are affected in anoxia which are most sensitive to deficient supply of oxygen.

MEDICINE AND THE WAR

ARMY

ARMY NURSE SHORTAGE GRAVE

Major Gen Norman T Kirk, Surgeon General of the Army recently disclosed the seriousness of the present shortage of army nurses at a ceremony in which Col Florence Blanchfield, superintendent of the Army Nurse Corps, accepted an oil portrait of an army nurse painted by a soldier in an effort to promote nurse recruiting. General Kirk stated that the shortage of nurses in the Army is acute and is growing more so every day. He said that 40,000 civilian registered nurses in the United States who are eligible for service in the Army Nurse Corps may have been "lulled by the false impression that is prevalent in certain quarters that the war in Europe is practically over."

The painting, presented to Colonel Blanchfield by Private Rudolf Bernatschke of the Recruiting Publicity Bureau U S Army, has already been made into a poster in the current drive to obtain 10,000 more army nurses. The painting depicts a blue eyed blonde second lieutenant of the Army Nurse Corps in bold relief, with an ambulance in the background. The poster, which has been distributed throughout the nation by the Recruiting Publicity Bureau, emphasizes that "Nurses Are Needed Now!" and carries the message "If you are a registered nurse and not yet 45 years of age apply to the Surgeon General, United States Army, Washington 25 D C or to any Red Cross procurement office."

SOUTHERN SURGICAL ASSOCIATION MEETS AT ASHFORD GENERAL HOSPITAL

Approximately 100 members of the Southern Surgical Association attended a preliminary meeting at the Ashford General Hospital, December 4, prior to their regular meeting at Hot Springs Ark. Following an address of welcome by the commanding officer, Col Clyde M Beck, the following clinical papers were presented by members of the hospital staff: Varus Deformity in Lower Third Humerus Fractures, Capt James W Riley, Choice of Anesthetic in Prolonged Operations, Capt William H Galin, Osteomyelitis the Use of Skin Grafts, Major Robert P Kelly, Repair of Skull Defects, Major George L Maltby, Penicillin Therapy in Gas Gangrene Osteomyelitis and Cranial Injuries, Capt F W Cooper, War Wounds of the Urogenital Tract, Major George C Prather, The Circulation in Arteriovenous Fistula, Major Milton L Kramer, Vascular Injuries of Warfare, Col D C Elkin. The papers were discussed by Major Gen Norman T Kirk, Surgeon General of the Army, Dr Alton Ochsner, president of the Southern Surgical Association, Dr Frederick Collier, Ann Arbor Mich, Dr John Albert Key, St Louis, and Dr Rudolph Matas, New Orleans.

DRS MAXSON AND BRIDGMAN COMMENDED

Major Gen Philip Hayes commanding general of the Third Service Command presented a certificate of commendation recently to Dr Charles W Maxson, Baltimore, for meritorious work as director of civilian medical examiners at the Fifth Regiment Armory induction center. General Hayes also awarded a certificate to Dr Eveleth W Bridgman, Baltimore, chairman of the examiners. The commendation of Dr Maxson said that since November 1940 he had "contributed materially to the war effort in his role of liaison between the civilian medical examiners of the state and the armed forces induction station. He has rendered notable and distinguished service in his keen judgment and marked acumen in appointing civilian medical examiners who were recognized as outstanding specialists in their respective fields and who were respected by the entire

citizenship of the state. His zeal for duty, both day and night, has led to innumerable sacrifices in his private life, all given with unstinting devotion."

Dr Maxson graduated from the College of Physicians and Surgeons of Baltimore in 1910, and Dr Bridgman graduated from Johns Hopkins University School of Medicine, Baltimore, in 1912.

MEDICAL ADMINISTRATIVE CORPS OFFICERS

The thirty-fourth class of the Camp Berkeley Medical Administrative Corps Officer Candidate School graduated on November 15. Col Taylor Darby, 12th Medical Training Regiment, commander, presented the diplomas, and the graduation was presided over by Lieut Col John A Nave, assistant commandant of the school.

The thirty-fifth class of the Camp Berkeley Medical Administrative Corps Officer Candidate School graduated on December 6.

ARMY AWARDS AND COMMENDATIONS

Captain William N Heffner

The Silver Star was recently presented to Capt William N Heffner, formerly of Northport, N Y, 'for gallantry in action against the enemy in Normandy, France. On July 19, 1944 during the attack in the vicinity of —, Capt Heffner established his aid station well forward in order that more effective evacuation might result and from there coolly administered medical aid to the seriously wounded while under decimating enemy fire. In addition, Captain Heffner, from a point well beyond his aid station, in an area which was constantly under enemy fire, personally supervised the evacuation of the wounded. At one time Captain Heffner, with complete disregard for his own safety, conducted searching parties looking for casualties in areas which were under intense enemy fire. During the course of the action Captain Heffner courageously led a medical party into a sector where part of a unit had been surrounded by enemy fire and removed the wounded to a point of evacuation. As a result of his heroic actions the casualties received the most prompt medical attention, undoubtedly saving the lives of the seriously wounded. Such actions reflect great credit on himself and on the military service." Dr Heffner graduated from Georgetown University School of Medicine, Washington, in 1940 and entered the service Oct 22, 1941.

Captain Roger E Watson

Capt Roger E Watson, formerly of Perrysburg, Ohio, was recently awarded the Silver Star Medal. His citation reads "During the entire period of June 6 to 15, 1944 in France his untiring efforts with his unit in immediate contact with the enemy exhibited outstanding judgment as a soldier and a surgeon. It was largely because of his excellent supervision and instructions to others in tactical situations while under enemy fire that he could leave our own forces three times to render medical aid to wounded French civilians. On one occasion eight Germans surrounded the house in which he was attending a wounded French child. Because of his coolness and dignity of bearing the enemy withdrew and permitted him to complete his work and return to our lines. His courage, skill and ability reflect great credit on himself and the military service. Dr Watson graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1941 and entered the service in September 1942.

Captain Hillard A Tolliver

Capt Hillard A Tolliver, formerly of Charles City, Iowa, has been awarded the Bronze Star for heroic achievement in action Battalion surgeon in the 91st Division on the 5th Army front, he was cited for his courage in administering first aid on the field of battle under intense enemy shell fire. Captain Tolliver volunteered to go forward to an area under intense enemy artillery and mortar fire when medical aid men were casualties and first aid was needed. Although shells burst near him, he administered first aid and blood plasma, saving the lives of many of the wounded. Dr Tolliver graduated from the State University of Iowa College of Medicine, Iowa City, in 1929 and entered the service Aug 21, 1942.

Captain Raymond Wheeler

The Silver Star and the Purple Heart were recently awarded to Capt Raymond Wheeler, formerly of Sanford, N C, for bravery and for wounds received in action. Dr Wheeler is now with a tank battalion in the European theater of war as a surgeon in the Medical Corps. He graduated from Washington University School of Medicine, St Louis, in 1943 and entered the service in January 1944.

Captain Edward J Horodko

The Bronze Star Medal was recently awarded to Capt Edward J Horodko, formerly of Chicago, for "meritorious achievement in connection with military operations against the

enemy at New Georgia, Solomon Islands, from July 22 to Sept 8, 1943." Dr Horodko graduated from Loyola University School of Medicine, Chicago, in 1941 and entered the service July 25, 1941.

Captain William N Baker

Capt William N Baker, formerly of Pueblo Colo, has been awarded the Soldier's Medal and the Presidential Citation. This award was for rescuing two officers from drowning. The rescue was in darkness and at complete disregard for his own safety. Dr Baker graduated from Northwestern University Medical School, Chicago in 1938 and entered the service July 29, 1941.

Major John A Burden

The Bronze Star Medal was recently awarded to Major John A Burden, formerly of Maui, T H, for "meritorious services against the Japanese forces at New Georgia and Vella Lavella, British Solomon Islands, from July 21 to December 18, 1943." Dr Burden graduated from the University of Louisville School of Medicine in 1936 and entered the service Dec 20, 1941.

Captain Elmer G Lampert

Capt Elmer G Lampert, formerly of Wheaton Ill, has been awarded the Bronze Star Medal for 'action outside the line of duty' in the European theater. Dr Lampert was in the Netherlands the last time he wrote his family. He graduated from Loyola University School of Medicine, Chicago, in 1940 and entered the service Aug 25, 1941.

NAVY**SCHOOL OF AIR EVACUATION
OF CASUALTIES**

Vice Admiral Ross T McIntire, Surgeon General of the Navy, recently announced the establishment of the Navy School for Air Evacuation of Casualties, which will introduce flying navy nurses for the first time. Scheduled to be launched at the U S Naval Air Station, Alameda, Calif, in mid-December, the school's first class will consist of 24 nurses and 24 pharmacist's mates. On completion of training, which will include flight indoctrination within the continental limits, the nurses and hospital corpsmen will report for duty with an air evacuation task unit with the fleet in the Pacific.

Although the Navy and Marine Corps pioneered in aerial evacuation of casualties—the South Pacific Combat Air Transport alone moved more than 25,000 patients, beginning with the Solomons operations in 1942—there has never been, until now, any formalized instruction of medical personnel making the flights. Naval flight surgeons who are especially trained in aviation medicine and air evacuation are exceptions. In the past, evacuees have been attended en route by hospital corpsmen in most instances.

Directed by the Deputy Chief of Naval Operations for Air to set up the new medical organization, the Bureau of Medicine and Surgery had the active cooperation of Naval Air Transport Service and the Bureau of Naval Personnel in planning the program. A number of VRH squadrons have been designated for the special duty. In addition to its regular flight and ground personnel, each twelve plane squadron will operate with 1 flight surgeon, 24 flight nurses, 1 hospital corps officer and 24 pharmacist's mates.

Ground school instruction will be under the cognizance of the medical department of the Naval Air Station at Alameda. Flight indoctrinal training will be directed by the Naval Air Transport Service, West Coast Command. Each squadron will train as a unit. All personnel are being selected carefully, for physical and professional qualifications. A distinctive working uniform, now being designed, will be worn by the flight nurses. Together with the hospital corpsmen, they will receive flight pay. Lieut (jg) Mary Ellen O'Connor, Nurse Corps, U S Naval Reserve, will serve as flight nurse in charge. She holds the record among American women for hours and miles in the air: 2,500,000 miles and 8,800 hours.

Capt J C Adams, Medical Corps, U S Navy, Chief of the Division of Aviation Medicine, had general supervision of the plans for establishment of the School for Air Evacuation of Casualties. Assisting him were Capt Leon D Carson (MC), U S N, liaison officer with Naval Air Transport Service, and Capt Sue S Dauser, Nurse Corps, U S N, superintendent of the Navy Nurse Corps.

NAVY AWARDS AND COMMENDATIONS**Lieutenant Frank Martin Hall**

The Navy Cross was recently awarded to Lieut Frank Martin Hall, formerly of Jamestown, N Y. The citation accompanying the award read "For extraordinary heroism as medical officer in charge of a naval beach party medical team during the invasion of the coast of France on June 6, 1944. Forced to swim 3 miles to shore when his own landing craft was sunk during the initial assault, Lieutenant (then Lieutenant, junior grade) Hall gallantly carried on his mission with such meager supplies as he was able to salvage from the dead and wounded. Completely unmindful of his own danger he labored with untiring zeal under the terrific fire of the enemy, resolutely assuming command of all medical work on an additional beach when it was determined that the officer in charge was missing in action and, despite the extreme hazards and the grueling strain, skillfully covered two beaches without relief until the afternoon of D plus two days. His splendid example of leadership and courage and his valiant devotion to the fulfillment of a vital and perilous mission reflect the greatest credit on Lieutenant Hall, his high professional integrity and the United States Naval Service." Dr Hall graduated from the University of Buffalo Medical School in 1942.

Lieutenant Robert E Walker

Lieut Robert E Walker, formerly of Livingston, Mont, was recently cited by the Navy Department for heroism under fire during the invasion of Guam. Dr Walker landed with the first wave of Marines on Guam Island, and he and five other physicians had set up an advanced medical post and were performing major surgical operations within thirty minutes after firing had started. The post was set up in a wrecked concrete house within range of enemy machine gun and artillery fire. Dr Walker graduated from the Medical College of Virginia, Richmond in 1936 and entered the service in November 1942.

MEDICAL KITS FOR SCHOOLS
IN EUROPE

The American Junior Red Cross is sending medicines sufficient for the needs of 1 000 000 school children in Yugoslavia Greece and Belgium The medicines in question are contained in kits now being purchased at a cost of \$87 500 Each kit will contain approximately thirty different standard medical items such as acetylsalicylic acid boric acid, soap and gauze The kits are designed to serve 400 children and are distributed to schools in the countries in question through the Joint Commission of the International Red Cross Committee Under this arrangement kits may be sent to occupied areas as well as those that have been liberated A total of 2 500 kits is being shipped, 1 000 to Yugoslavia, 1,000 to Greece and 500 to Belgium

These medical kits are being paid for from the American Junior Red Cross National Childrens Fund This fund is maintained by voluntary contributions on the part of the children and the purchase of medical kits is one of the ways in which the Junior Red Cross is participating in the rehabilitation of children in the liberated countries of Europe Another project is the classroom gift boxes which members of the Junior Red Cross have packed and which have been sent to

European countries for distribution among school children Altogether 450,000 of these boxes, each containing twelve articles such as crayons, pencils, rulers, sewing kits, soap and wash cloths have been packed and shipped for distribution

QUOTA RESTRICTIONS OF MEDICAL
X-RAY EQUIPMENT FOR
CIVILIANS

The X Ray Industry Advisory Committee was recently informed by the War Production Board representatives that the present quota restrictions on the manufacture of medical x ray equipment for civilian use cannot be lifted until certain components become less critical Components used in the manufacture of x ray equipment are also needed for combat equipment and there appears to be little likelihood that military demand for these components—including fractional horsepower motors shock proof cable, small transformers, meters, capacitors and resistors—will decrease sufficiently to justify removal of quota restrictions until after victory in Europe

A manufacturer's shipments of medical x-ray equipment for civilian use is limited to 75 per cent of his average annual shipments during 1937, 1938 and 1939 figured on the basis of dollar value This quota applies only to shipments within the United States to its possessions and territories and to Canada

WISCONSIN VETERANS' HOSPITAL

It was reported recently that 300 acres of ground and school facilities at Tomah Wis, will be turned over to the Veterans Administration for use as a Veterans Neuropsychiatric Hospital The Army has discontinued operation of a military radio school there and negotiations have been under way for some time for the transfer to the Veterans Administration The Veterans Administration announced that it plans to build a \$4 880 000 1 328 bed neuropsychiatric hospital on the site The hospital will serve southern Wisconsin, eastern Iowa and northern Illinois

AIR SHIPMENTS OF RED CROSS MEDICINES TO CHINA ESTABLISH
NEW RECORD

Air shipments of medicine into China set a new record in September with 44 tons flown over the Himalaya Mountains from India according to Basil O'Connor chairman of the American Red Cross The original Red Cross program of medicines for China called for shipment of 10 tons per month, but increased need of drugs and medicines and added flying facilities have led to an increase that will provide 40 to 50 tons a month September shipments were of particular importance, since they were made up largely of sulfonamide drugs, some of which were flown immediately into an area where there had been outbreaks of plague Medical shipments are sent to Calcutta shipped overland to the Assam air fields and flown from there into China

COLONEL ROWNTREE GIVEN SCROLL
OF HONOR

Col Leonard G Rowntree chief of the Medical Division of the Selective Service, received a scroll of honor recently by the New York State Committee on Physical Fitness The scroll praised Colonel Rowntree for his interest, understanding and efforts in behalf of the physical fitness of a nation at war and the welfare of the youth of the future

DOCTORS ASKED TO AID ITALY

Prof Arturo Castiglioni of Yale University School of Medicine New Haven, Conn is organizing the doctors of America into a unit to aid the needy people of liberated Italy with surgical instruments and medical supplies American Relief for Italy, Inc, recently announced Gifts donated by doctors will be shipped overseas through the agency a member of the National War Fund

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Dec 18 1944

Men Now in Army to Continue College Courses After War

Although the percentage of medical students is not given, figures released by the War Department for publication as of December 20 reveal that 500,000 of approximately 6,750,000 men now in the Army have definite plans to return to full time school or college courses. The Information and Education Division of the Army Service Forces bases the figure on a cross section survey of troops in the United States and overseas. An additional 300,000 are seriously considering resuming their education on a full time basis but are undecided or have conflicting job plans. Still another 1,200,000 men intend to attend part time school or college. Governing factors are the length of the war and prevailing economic conditions. No indication is given as to how anticipated resumption of studies will affect the flow of graduates from medical schools, although it is stated unofficially that most young men whose medical courses were interrupted will probably wish to resume their studies toward a medical career.

Proposed Appropriation of \$2,000,000 Federal Aid to Cancer Research

Federal aid to cancer research, with an initial appropriation of \$2,000,000 to the National Cancer Institute, the federal agency which already leads in cancer research, was proposed by E V Cowdry, Ph D, of Washington University and the Barnard Free Skin and Cancer Hospital, St Louis, to the Senate Subcommittee on Health and Education the past week. Dr Cowdry suggested that the plan might serve as a pilot program for future federal aid to medical research. He pointed out that cancer is the most dreaded of all diseases, and although heart, artery and kidney diseases are greater killers they are more merciful. The Cancer Institute, he suggested, would disburse the money to other institutions of recognized ability to conduct both short and long term research on cancer. Such institutions would be free to accept funds also from private sources. Additional federal aid, he said, would increase the value accruing from private donations to cancer research. An unusual feature of the proposal is that Congress should authorize the issue of a special series of government bonds to be nontransferable and bear 5 per cent interest. These could be purchased only by privately managed, nonprofit colleges and universities. In this way the less well endowed could get federal aid without giving up individual freedom.

Compromise Offered on Social Security Legislation

Representative John D Dingell, Democrat of Michigan, sponsor of the omnibus social security bills—introduced eighteen months ago but on which nothing has been done since not even committee hearings—has offered to drop or compromise some controversial parts of the program. To salvage portions of the project he proposes that the big bill be split into several sections to be submitted to the new Congress opening in January. Mr Dingell said that he considers some form of public health and hospitalization insurance, with wage earners helping to pay for it as first on the list of items he believes should be made law, but he is against socialized medicine, which has been opposed by medical organizations. He suggests a simple system under which a poor man can get money to pay for medical or dental attention or hospital care when his family needs it. Under his

plan, doctors and dentists would not be employed directly by the government, but there would be supervision of the system by the United States Public Health Service. "There wouldn't be any big medical bureaucracy running all the doctors and hospitals from Washington," Mr Dingell explained. Some people may have been able to read that into our bills, but it is a false alarm. He contends that it would benefit the medical profession as well as the masses of the people if more people could pay for medical attention. They would not be so slow in asking for it. The second item on his program would be inclusion of as many as possible of the 20,000,000 American workers who do not have guaranties of old age and survivors' insurance like the 40,000,000 now covered.

Importance of Postwar Research Stressed

Research must not be neglected after the war, Brig Gen James S Simmons, chief of the preventive medicine section of the Office of the Surgeon General, informed the Kelley subcommittee. "We will neglect it at our own risk," he warned. "This nation affords unlimited natural resources in scientific talent which need only opportunity and facilities to bear upon the health programs of the nations in peace or war."

Dr Lewis H Weed, chairman of the division of medical sciences, National Research Council, said that federal aid to medical research should be planned with regard to the total medical problem, which includes medical practice, hospitals, preventive medicine and public health.

Several medical authorities told the subcommittee that the amazing speed with which such spectacular health aids as penicillin, DDT and blood substitutes, including plasma, were developed by federally sponsored and aided research during the war was evidence of what such assistance to medical research can accomplish.

Pensions for Widows and Children of First World War Veterans

President Roosevelt has signed the bill providing pensions for widows and children of deceased veterans of the first world war. The cost is estimated at \$37,000,000 in its first year. The program provides benefits up to \$74 a month for families of men who served in the first world war. Pensions are provided regardless of the cause of death. Previously pensions were allowed widows and children only if the veteran died of war service disability and if he died of some other cause but had been disabled in the war. Widows without children will get \$35 a month, with one child \$45 and \$5 for each additional child. The child of a deceased veteran whose mother also is dead will get \$18, two orphans will receive \$27, three will get \$36, and \$4 is provided for each additional orphan. Veterans must have served at least ninety days for families to become eligible.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARKANSAS

Dr Fatherree Appointed Registrar of Vital Statistics—Dr Leroy L. Fatherree, health officer of Little Rock, has been appointed registrar of vital statistics for the city. The appointment is a part of the recent transfer of the vital statistics bureau from the city clerk's office to the health department.

CALIFORNIA

Fatal Case of Botulism—Home packed string beans were responsible for the death of a person from botulism in southern California recently.

Changes in Health Personnel—Dr John O. Rafferty, Santa Rosa, recently resigned as deputy director of the California State Department of Public Health to become resident physician at the Santa Cruz County Hospital. The city of Newman recently transferred the administration of its public health affairs to the Stanislaus County Health Department with headquarters at Modesto. Dr James E. Thompson had been head health officer.

Woman Wills Body and Fund for Research—Miss Edith Clawson, who died recently at the age of 65 from a glandular disorder, provided in her will that her body be used for research and bequeathed a fund of \$250,000 to Dr Edward F. F. Copp of the Scripps Metabolic Clinic, La Jolla, to carry out the study. The will stated that Miss Clawson offered her body to serve 'in medical and scientific research.' It also contained a bequest of \$50,000 to the Mercy Hospital, Hamilton, Ohio.

COLORADO

State Medical Election—Dr George H. Unfug, Pueblo, was chosen president elect of the Colorado State Medical Society at its recent annual meeting in Denver, and Dr Edward R. Mugrage, Denver, was installed as president. Other officers include Drs Harry C. Bryan, Colorado Springs, vice president; John S. Bouslog, Denver, secretary; and Lloyd R. Allen, Colorado Springs, treasurer.

DISTRICT OF COLUMBIA

Portrait of George Vaughan—An oil portrait of Dr. George Tully Vaughan, emeritus professor of surgery, Georgetown University School of Medicine, was presented to the medical school on October 16 by members of the Medical Alumni Association. The portrait is the work of John Bjorn Egeli, Washington artist. Dr. Vaughan graduated at the University of Virginia Department of Medicine, Charlottesville, in 1879. He was professor of surgery at Georgetown University and chief of surgery at the Georgetown University Hospital from 1897 to 1933 and since then has been serving as a member of the executive faculty and council and as administrative adviser to the medical school. A plaque showing a photograph of the portrait and an engrossed scroll of the resolutions of the alumni association were presented to Dr. Vaughan.

ILLINOIS

Chicago

Personal—Lieut. (jg) Charles E. Nyberg, who served as assistant to Dr. Rosco G. Leland, Director of the Bureau of Medical Economics, American Medical Association, participated in the Normandy and southern France invasions. Lieutenant Nyberg served on the staff of the division commander of attack transport of the amphibious force.

KANSAS

School Health Study—Clair E. Turner, Dr. P. H., formerly professor of public health, Massachusetts Institute of Technology, Cambridge, Mass., is conducting a statewide school health study in Kansas under the direction of Dr. Floyd C. Beelman, Topeka, secretary and executive officer of the state board of health, and Miss May Hare, health education coordinator in the state health department. The study aims to formulate policies, set up standards and make specific recommendations for building strong local health programs.

KENTUCKY

Physician Named Chairman of Negro Health Committee—Dr. Maurice F. Rabb, Shelbyville, has been named chairman of the health committee of the Negro Affairs Commission, which was created late in September by an executive decree of Governor Simeon S. Willis to recommend 'practical solutions to problems confronting Negroes in Kentucky in the fields of education, health, housing, economics and civil affairs.' The commission organized itself into five units, one of which is that headed by Dr. Rabb.

Jane Crawford Day—Governor Simeon S. Willis recently designated December 13 as Jane Todd Crawford Day in Kentucky in honor of the woman who submitted to the first operation for removal of an ovarian tumor, conducted by Dr. Ephraim McDowell. The occasion is of importance in Kentucky's medical history and a monument in honor of both Mrs. Crawford and Dr. McDowell was erected in Danville, where the operation was performed, by the Kentucky State Medical Association.

Personal—Dr. Addie M. Lyon, Frankfort, state director of hospitals and mental hygiene, on November 1 assumed the additional duties of acting superintendent of the Central State Hospital, Lakeland. Dr. Charles E. Youmans, superintendent of the State Institution for the Feeble-minded, Frankfort, will become acting assistant director of the state division of hospitals and mental hygiene in addition to his present work. Dr. Lyon will be assisted at Lakeland by Dr. Frank L. Peddicord, who was named acting superintendent when Dr. Isham Kimbell resigned several weeks ago.

LOUISIANA

Student Prizes Awarded—Ernest C. Faust, Ph.D., professor of parasitology, Tulane University of Louisiana School of Medicine, New Orleans, gave the Ivy Day address during the present commencement exercises of the medical school. His subject was 'The Heritage and Tradition of the Tulane University School of Medicine.' The prizes awarded to students during the ceremonies included the following:

Querens Rives Shore Award for the best senior thesis on a subject in the field of cardiology to Dr. Ross Frederick Bass, Chelsea, Mass., for his thesis, 'An Evaluation of the Cardiac Function Tests.'

Walter Reed Memorial Medal of the Louisiana State Medical Society for the best senior thesis on a subject in the field of tropical or preventive medicine to Dr. Emile Augustus Bertucci, Jr., New Orleans, for his thesis, 'Spirochetel Jaundice.'

Jacob C. Geiger Medal for the best senior thesis on a subject in the field of tropical or preventive medicine to Dr. Arnold Harvey Baum, San Francisco, for his thesis, 'Public Health Aspects of Rheumatic Heart Disease.'

Sidney K. Simon Prize for the best senior thesis on a subject in the field of digestive diseases, nutrition or tropical medicine to Dr. Charles Daniel Knight, Shreveport, La., for his thesis, 'Filariasis: A Future Problem in the United States.'

Award by the professor of medicine for the best senior thesis on a subject in the field of internal medicine, given to two seniors: Drs. James Clinton Prose, Fairfield, Ala., for his thesis, 'Liver Function Tests,' and John W. Bassett, Philadelphia, for his thesis, 'Friedreich's Ataxia.' Drs. Jura Arsenow and Pascal Gayle Batson, Jr., New Orleans, received honorable mention for their theses, 'The Therapy of Amebiasis' and 'The Blood Supply of the Heart,' respectively.

Isadore Dyer Medal for the highest average for the four years of medical school to Dr. John Winton Deming, New Orleans.

MASSACHUSETTS

Symposium on Bursitis—The New England Society of Physical Medicine devoted its first meeting of the season, November 15, at the Hotel Kenmore, Boston, to a symposium on 'Treatment of Bursitis of the Shoulders.'

Research Fellowship Named for Physician—The Helen Putnam Fellowship for advanced research has been established at Radcliffe College, Cambridge, bearing the name of the physician who gave the endowment for the award. The fellowship carries a stipend of \$1,750 and will be awarded each year for an eleven month period to a resident fellow and will also provide a subsidy for the publication of manuscripts approved by the Radcliffe committee on publications. It will be available to mature women scholars in the field of genetics or mental health, and appointments will be limited to candidates submitting a plan of research that is already under way. Dr. Putnam, who graduated at Vassar College, Poughkeepsie, N. Y., received her degree in medicine at the Woman's Medical College of Pennsylvania, Philadelphia, in 1889. The first appointment to the fellowship will be made in February 1945 for an award to be dated October 1 of the same year.

MINNESOTA

Another County Accredited for Tuberculosis Control—Martin County was recently accredited for the control of human tuberculosis, the ninth county in the state to receive this recognition under a program sponsored by the Minnesota

Department of Health and the state medical association as well as local cooperating authorities. The record in Martin County was far below that required for accreditation. The tuberculosis death rate is 32 per hundred thousand population for the current five year period, which is the lowest in the state, and the rate of infection among high school seniors of the county in a recent survey is less than 7 per cent. According to *Everybody's Health*, requirements for accreditation call for a death rate of less than 10 per hundred thousand and an infection rate among high school seniors of less than 15 per cent.

MISSISSIPPI

Changes in Health Officers—Dr Kenneth W Navin has been named health officer of Yazoo City—Dr Henry G Waldrop has been appointed in charge of the Prentiss County Health Department, Booneville—Dr Norris C Knight, Meridian, has been appointed director of the Washington County Health Department

MISSOURI

Personal—Dr Edward L Burns, associate professor of pathology and bacteriology, Louisiana State University School of Medicine, New Orleans, is serving for several weeks as visiting associate professor of pathology at Washington University School of Medicine, St Louis

The First John Auer Lecture—The Lambda chapter of Phi Beta Pi has established a lectureship at St Louis University School of Medicine in honor of Dr John Auer, professor and director of the department of pharmacology. The first lectureship was given November 29 by Dr Warfield T Longcope, professor of medicine at Johns Hopkins University School of Medicine, Baltimore, on "Allergic and Toxic Reactions of the Sulfonamide Drugs"

Officers of New Medical Service—Dr Carl F Vohs, St Louis, was elected president of the Missouri Medical Service, a new statewide medical-surgical plan sponsored by the Missouri State Medical Association (THE JOURNAL, July 22, p 859). Other officers include Dr Howard B Goodrich, Hannibal, and Louis W Reys, managing director of the Springfield Chamber of Commerce, vice presidents Dr Raymond O Muehler, St Louis, secretary, and George M Berry, St Louis, treasurer. The new plan, enrolment for which will begin January 15, includes medical and surgical illness in hospitals under an allowable benefit schedule, and payment will be made directly to the physician. Monthly dues for single members will be 85 cents, for families, regardless of dependents, \$2.25 while dues for man and wife will be \$1.85 a month

NEBRASKA

Personal—Dr Henry R Miner, Falls City, recently completed fifty years in the practice of medicine—Dr Frank P Murphy, Omaha, has been appointed chief medical examiner on the main line of the Union Pacific railroad

Dr Frary Resigns—Dr Reginald A Frary, Lincoln who has been a member of the staff of the Nebraska Department of Health, has resigned as director of the division of venereal disease control. During his period of association with the department, Dr Frary has spent one year in special study at Johns Hopkins University in Baltimore

NEW YORK

Sidney Madden to Join Emory University—Dr Sidney C Madden, associate professor of pathology, University of Rochester School of Medicine and Dentistry, Rochester has accepted a position as professor of pathology and head of the department at Emory University School of Medicine, Atlanta. The appointment will be effective in March and fills the vacancy that occurred when Dr Roy R Kracke left Emory to become dean of the University of Alabama School of Medicine, Birmingham

Prize Awards—The Rochester Academy of Medicine announces three prizes the competition for which will close March 1. The John W McCauley prize of \$25 accompanied by a certificate of merit, will be given for the best case history offered by a first or second year house officer of an accredited hospital in Monroe County. This award is made possible through the generosity of Mrs David B Jewett. The Taylor Instrument Companies prize of \$100, accompanied by a certificate of award, will be given for a thesis contributing to our knowledge of clinical medicine (including internal medicine, surgery, obstetrics, pediatrics or other subdivision) attained by deduction from accurate observation of cases, review of the literature, laboratory studies and public health survey or a combination of these. Competition for this prize is open to

any doctor of medicine whose degree was received from an approved medical school since April 30, 1940 and who is either a bona fide resident of Monroe County or is on the staff of an accredited medical institution located in Monroe County. This award has been made possible through the generosity of the Taylor Instrument Companies. The Paine Drug Company prize of \$100, accompanied by a certificate of award will be given for a thesis contributing to our knowledge of clinical medicine (including internal medicine, surgery, obstetrics, pediatrics or other subdivision) attained by deduction from accurate observation of cases, review of the literature, laboratory studies and public health survey or a combination of these. Competition for the prize is open to any member of the Rochester Academy of Medicine in good standing on May 1, 1944. This award has been made possible through the generosity of the Paine Drug Company. The theses should be sent to the Rochester Academy of Medicine, 1441 East Avenue on or before March 1. The thesis shall in no way bear the identity of the author but should be included with a sealed envelop carrying this identification

New York City

Course on the Heart—The Mount Sinai Hospital announces that a course in fluoroscopy and x-ray of the heart and great vessels will be given January 5-March 23. Drs Marcy L Sussman and Arthur Grishman will give the course which is a repetition of one given earlier

Portrait of Dr Joachim—On November 21 unveiling ceremonies were held at the Medical Society of the County of Kings of a portrait of the late Dr Henry Joachim, president of the society in 1936. The portrait was presented by a group of his friends and former associates in the various hospitals with which he was affiliated. Dr Joachim, who died Aug 18, 1941, held a number of positions with his county medical society, serving several terms as censor, delegate to the state society, trustee and vice president. The portrait was unveiled by Dr Benjamin M Eis, Brooklyn who was associated with Dr Joachim for many years

Amendment on "Fee Splitting"—On December 7 the New York Academy of Medicine adopted an amendment to its constitution stipulating that both "fee splitting and receiving a rebate are unethical and in violation of the constitutional regulations of the academy. The amendment further empowered the academy's council, by a three-fourths vote of its total membership, to expel any fellow found guilty. Dr William W Herrick, professor of clinical medicine, Columbia University College of Physicians and Surgeons was elected president of the academy for a term of two years. Among other officers chosen were Drs J Burns Amberson Jr, vice president for a term of three years, and Shepard Krech, treasurer for three years

Friday Afternoon Lectures—Subsequent lectures included in the Friday afternoon series at the New York Academy of Medicine which opened November 3 (THE JOURNAL, October 14, p 445) are

Dr Charles L Hoagland, The Therapy of Liver Disease, January 5
Dr H McLeod Higgins, Present Trends in the Treatment of Pulmonary Tuberculosis, January 12
Dr Robert F Watson, Modern Concept of Rheumatic Fever, January 19
Dr Howard W Haggard, New Haven Conn, Problem of Alcoholism, January 26
Dr Fred W Stewart, Hormone Therapy and Human Mammary Cancer, the L Duncan Bulkley Lecture, February 2
Dr Philip M Stimson, Specific Remedies in the Prevention and Treatment of the Exanthemata, February 9
Dr Nolan D C Lewis, Shock Treatment of Psychoses, February 16

OHIO

Dr Quigley Goes to Tennessee—John P Quigley, Ph D, a member of the staff of Western Reserve University School of Medicine, Cleveland, since 1929 and professor of gastrointestinal physiology since 1943, has accepted an appointment as professor of pharmacology and chief of the division at the University of Tennessee College of Medicine, Memphis

Friedlander Lecture—Dr Eugene A Stead Jr, Atlanta Ga, delivered the Alfred Friedlander Lecture at a joint meeting of the heart council of the Public Health Federation and the Academy of Medicine of Cincinnati in Cincinnati, December 5. His subject was "Mechanism and Treatment of Shock and Allied Disorders"

Grant for Research on Glaucoma—The Snyder Ophthalmic Foundation has given a grant of \$6,500 a year for a period of two years to the Toledo Hospital Institute of Medical Research for research on the physiology of the eye especially in relation to glaucoma. The grant will be extended, depending on the results obtained in the first two years. According to

Dr Bernhard Steinberg director of the Toledo Hospital Institute of Medical Research because of the war research will be delayed until a physiologist with specialized training in the eye can become available

OKLAHOMA

University News—Louis Alvin Turley, Ph.D., who retired September 1 as professor of pathology at the University of Oklahoma School of Medicine, Oklahoma City (THE JOURNAL November 18 p. 781) recently gave to the library of the medical school a doctor's saddlebag given him by Dr. Nancy D. Campbell, Las Vegas, N. M., of the U. S. Indian Service. The bag was used in the Rio Arriba country, New Mexico, in the period before the horse and buggy made its appearance. By releasing the straps on either end of the bag it divides into two parts which hang over the skirt of the saddle.

PENNSYLVANIA

Personal—Dr. Marvin R. Evans, Coal Dale, has been appointed chief surgeon of the Lehigh Navigation Coal Company in Panther Creek Valley to succeed the late Dr. Robert H. Kistler, Lansford.

Philadelphia

Graduate Courses—The graduate department of public health and preventive medicine of the University of Pennsylvania School of Medicine announces that a course in industrial medicine and hygiene will begin January 2 under the direction of Dr. Charles-Francis Long. A graduate course in the control of communicable diseases will begin January 6 with emphasis placed on the value and technique of public health education in preventing disease. Additional information may be obtained from the director, department of public health and preventive medicine, University of Pennsylvania, Philadelphia 4.

Graduate Lectures—A series of graduate lectures sponsored by the Woman's Medical College of Pennsylvania included a talk by Dr. William D. Stroud, November 22, on coronary disease and one on digitalis therapy. Drs. Samuel Bellet and William G. Leaman, Jr., discussed recent trends in the treatment of cardiovascular disease, December 6. Others in the series include:

Dr. Leandro M. Tocantins, Recent Advances in Hematology, January 3.
Dr. Edward Weiss, Recent Advances in Our Knowledge of Kidney Disease, January 17.

Dr. Weiss, Practical Aspects of Essential Hypertension, January 31.

Portrait of Dr. Croasdale—Special ceremonies were held November 29 to mark the unveiling of a portrait of the late Dr. Hannah T. Croasdale, presented to the Woman's Medical College of Pennsylvania by Miss Marjorie Trump and Mr. Charles Croasdale, Trump's granddaughter and grandson, respectively. The physician, Dr. Croasdale, was said to be the first woman physician to occupy a chair of gynecology serving the Woman's Medical College of Pennsylvania, where she graduated in 1880 as instructor in the department of surgery from 1875 to 1879 and professor of gynecology from 1880 to 1902 when she became emerita professor. Among the speakers at the ceremonies were Dr. Catharine Macfarlane, professor of gynecology who worked with Dr. Croasdale first as a student and then as an intern, and Rachel Bulley Trump (Mrs. Charles C. Trump), the artist who executed the portrait.

TEXAS

Society News—Arthur R. Colmer, Ph.D., department of botany and bacteriology, University of Texas, Austin, was elected November 18 secretary of the Texas branch of the Society of American Bacteriologists to succeed Dr. Gordon Worley, Jr., who resigned to enter the U. S. Navy. The election took place during the fall meeting of the Texas branch at the Baylor University College of Medicine, Houston, and was addressed, among others, by Howard W. Lundy, Dr. P.H., recently appointed director of health education of the Houston City Health Department and assistant professor of public health and preventive medicine of the Baylor University College of Medicine.

GENERAL

Orthopedic Surgeons Cancel Meeting—The thirteenth annual convention of the American Academy of Orthopedic Surgeons, scheduled to be held in Chicago, January 21-24, has been canceled. Dr. Myron O. Henry, 825 Nicollet Avenue, Minneapolis, is the secretary.

Crippled Children Society Changes Name—The formal name, National Society for Crippled Children and Adults, was adopted at the recent meeting in Chicago of the national group for crippled children. Col. Elbridge W. Palmer, Kingsport, Tenn., was reelected president of the society and Mr. E. I. Howenstine, Elyria, Ohio, is secretary.

Osborne Medal Goes to John Baker—The Osborne Medal of the American Association of Cereal Chemists will be presented to John Clark Baker, Ph.D., Montclair, N. J., during the 1945 meeting of the association in Toronto, Canada. The medal is awarded for distinguished contributions to cereal chemistry and related sciences. Dr. Baker is known for his many inventions in sanitary and pharmaceutical fields.

Society News—Dr. Vlado A. Getting, Boston, commissioner of health of Massachusetts, was recently chosen secretary of the Association of State and Territorial Health Officers to succeed Dr. George C. Rubland, Washington, D. C. Other officers of the association are Dr. Irl C. Riggan, Richmond, Va., president and Dr. Roy L. Cleere, Denver, vice president. The twenty-eighth annual meeting of the American Dietetic Association will be held at the Netherland Plaza Hotel, Cincinnati, October 15-19.

Robert Fischelis Chosen Secretary of Pharmaceutical Association—Robert P. Fischelis, Ph.D., chief chemist, drugs and health supplies branch, Office of Civilian Requirements War Production Board, has been elected to succeed the late Evander F. Kelly, Ph.D., as secretary and general manager of the American Pharmaceutical Association effective January 1. Dr. Fischelis, who has been executive secretary and chief chemist of the New Jersey Board of Pharmacy since 1926, resigned September 1 to devote more time to activities with the War Production Board.

The Process of Group Therapy—The American Group Therapy Association will hold its second annual meeting at the Russell Sage Foundation building, New York, January 12-13. The theme of the program will be "The Process of Group Therapy" and papers will cover treatment in groups of children, adolescents and adults and in rehabilitation of ex-servicemen. The American Group Therapy Association was organized Nov. 16, 1943, to stimulate interest and research in group therapy, issue publications, serve as a center for exchange of experience and provide consultation and training for group therapy. Offices of the association are 228 East Nineteenth Street, New York 3. Officers include S. R. Slavson, president, and George Holland, secretary-treasurer.

New Rulings of Board of Anesthesiology—The American Board of Anesthesiology, Inc., announces that beginning January 1 all new applicants must be graduates of a grade A school recognized by the board, must have completed a year's internship (preferably rotating) in a recognized hospital (as before) must have completed two years' special training in a residency approved by the board (formerly "recommended" now required) and must have completed five calendar years (including training) 100 per cent limited in the specialty. Applicants are reminded that regardless of qualifications they must be prepared to take written oral and practical examinations. Applications must be filed ninety days prior to examination. The next written examination will be held January 19 at various centers and the next oral examination preceding the scientific assembly of the American Medical Association.

Hospital Orderly Sentenced on Larceny Charge—Harry Ward, who has been working at various hospitals throughout the country as an orderly, was sentenced in Milwaukee on a charge of grand larceny, recently. Ward is said to have a long prison record under his aliases as George Hamilton, Harry Harder, William Ralph, George Marlowe, Harry Ford, Harry Woods and Thomas Irvin. He will be confined at Waupun but was granted a fourteen-day stay so that federal authorities might prosecute him on a narcotic charge. At various times his application for employment indicated that he was a former brakeman. He is 54 years of age, about 5 feet 9 inches in height and weighs about 136 pounds. His hair is gray with a widow's peak in front and he has brown eyes. Ward is believed to be a narcotic user but his racket appears to be stealing from patients in hospitals where he is working.

Vitamin D Patents Again Ruled Free—For the second time within seventeen months the U. S. Circuit Court of Appeals, ninth judicial district, San Francisco, ruled invalid the Steenbock patents covering production of the antirachitic vitamin D through the use of ultraviolet ray lamps according to the New York Times, November 25. The University of Wisconsin Alumni Research Foundation, Madison, to which Harry Steenbock, Sc.D., assigned the patents taken out in 1924, 1926 and 1933, collected \$7,478,558 from licenses up to Dec. 31, 1939, at the rate of \$900,000 in the final five-year period, it was stated. Judge William Denman wrote that on the evidence Dr. Steenbock's discoveries for the prevention and cure of rickets were a great boon to humanity but said that it was a public offense to withhold such processes from any or the principal foods of the rachitic poor or indeed from

those of any such sufferers" "Assuming that Dr Steenbock discovered, as he claims," he stated, "that the sun's rays coming from millions of miles away could irradiate foods with vitamin D and that this was the reason, unknown to them why farmers and coconut growers regarded their sun-cured hays and sun-dried copra as good foods, such a discovery does not entitle him to a patent on their processes" Judge William Healy agreed that Dr Steenbock did not invent anything but held that the court should stick to the issue as presented by the attorneys

Sugar Research Grants—More than a quarter of a million dollars has been allotted in six grants to scientists according to an announcement by the Sugar Research Foundation New York, December 8 The six recipients benefiting under these grants include

Dr L Emmett Holt Jr. department of pediatrics Johns Hopkins University School of Medicine Baltimore for studies relating to synthesis of B vitamins by bacteria in the human intestinal tract with special reference to the influence of various carbohydrates

Andrew P vanHook Ph D department of physical chemistry Lafayette College Easton Pa for study of the kinetics of sucrose crystallization

James M Neill Ph D department of bacteriology and immunology Cornell University Medical College New York for investigation of traces of serologically active polysaccharides in sugar

Curt P Richter Ph D, psychobiologic laboratory Johns Hopkins University, for investigation of nutritive values of soft and raw sugars and of the carbohydrate:thiamine ratios taken by rats allowed free selection of all required nutrients

John Haldi Ph D department of physiology Emory University School of Medicine Atlanta Ga for study of blood sugar levels in human subjects following high protein and high carbohydrate meals of isocaloric value

William V Cruess Ph D, chief Fruit Products Division Agricultural Experimental Station University of California Berkeley for study of sugar in quick freezing of fruit products

Carl W Borgmann Ph D engineering experiment station University of Colorado Boulder for pilot plant production of D fructose (levulose) from sucrose and investigation of methods for separating dextrose and levulose

Uniform Standards of Penicillin—On October 20 Sir Henry Dale president of the Royal Society, London, announced that international agreement had been reached by the health committee of the League of Nations on a uniform standard and unit of penicillin and that there could be no doubt that the workers in Great Britain and America and eventually throughout the world would be using the same standard dosage The agreement was reached at a meeting in London attended by representatives of Great Britain, United States, Canada, Australia and Free France According to the *British Medical Journal* Sir Henry Dale said that it was in 1921 that the health committee first took in hand the question of measurement of a number of biologic remedies in terms of their activity This was done in order to obtain international uniformity, so that 1 unit of activity would mean the same wherever it was prescribed The first agreements of this kind were obtained in the case of antitoxins notably the antitoxin of diphtheria Another example was the standardization of insulin in 1925 The same standard was adopted outside the League—in Russia, which was not then a member, and in the United States which never became a member, the same standard was continued in Germany and Italy after they had left the League Standardization was also applied to hormones and vitamins The *British Medical Journal* pointed out that the new international standard penicillin would be finally purified and crystallized in the United States but the material for this purpose would be freely supplied by manufacturers in Great Britain and the United States There was no substance in the talk about trade rings in the manufacture of penicillin The manufacturers in both countries had pooled their information from the very first and had given their results to the Medical Research Council, thus making the manufacture of penicillin during the war a real national effort

LATIN AMERICA

Health Activities—*Cuban Branch of Academy of Pediatrics*—The first meeting of the Cuban Branch of the American Academy of Pediatrics was held in Havana, August 30, with Drs Clifford G Grulee Evanston, Ill, secretary of the American Academy of Pediatrics, and Angel Vieta, Barahona, dean of the Medical School University of Havana, as guests of honor Consideration was given to the admission to the American Academy of Pediatrics of all Latin American pediatricians under the so called region 5

Conference on Hospital Administration—A conference on hospital administration was held in Lima, Peru December 3-16 under the auspices of the Inter-American Hospital Association cooperating with the Pan American Sanitary Bureau the Office of the Coordinator of Inter-American Affairs and the Peruvian government Representatives from the United States included Dr Malcolm T MacEachern, Chicago, chairman of the council of international relations for the American Hospital Association, Dr Donald C Smelzer, Philadelphia

president, and Dr Robin C Buerki Philadelphia of the American Hospital Association, Dr Claude W Munger New York president of the American College of Hospital Administrators, Mr James A Hamilton New Haven Conn representing the Inter-American Hospital Association, and the Rev John J Bingham New York of the council of Pan American Relations of the Catholic Hospital Association

FOREIGN

Funds for Health Work—The sum of \$900,000 was earmarked for medical work during the thirtieth annual convention of Hadassah, the Women's Zionist Organization of America, in Cleveland, November 13-16 The general program will include the initiation of a building fund for a new 250 bed tuberculosis hospital which will be erected in Palestine as a postwar project and which will be an integral part of the Rothschild-Hadassah University Hospital the chief unit of the Hadassah Medical Center on Mount Scopus Dr Haim Yassky Jerusalem, Palestine, director of the Hadassah Medical Organization, attended the Cleveland convention he made his first visit to the United States in 1932

Plan to Locate Royal Colleges on Same Site—The Royal College of Surgeons, in a recent annual report invited the Royal College of Physicians and the Royal College of Obstetricians and Gynaecologists to move to Lincoln's Inn Fields and share the surgeons' site The location of the three groups on the same site would assist in the development of a medical center According to the *Lancet* the college owns a freehold of numbers 35 to 45 Lincoln's Inn Fields, a site twice the size of that occupied by its buildings before the war, which would allow for the erection of additional buildings The museum of the college of surgeons is now located at Lincoln's Inn Fields, and the college is arranging for the return of its research laboratories, planning for the new professorship of human and comparative pathology (THE JOURNAL Nov 27 1943 p 851) and preparing space for the 27,000 museum specimens now stored in the country as well as a large number of new specimens

Deaths in Other Countries

Dr Carl von Noorden, known for his work in diabetes died in Germany according to a broadcast reported November 17—Dr Rafael A Bullrich, formerly dean of the faculty of medical sciences of the University of Buenos Aires died in Buenos Aires recently aged 67—Dr Julius Lowy, chairman of the Czechoslovak Medical Association in London and authority on occupational diseases, died in London November 25 aged 59

Government Services

Lawrence Kolb Retires

On October 31 Lawrence Kolb medical director U S Public Health Service, in charge of the mental hygiene division, Bureau of States Services, retired, concluding thirty-five years with the public health service Dr Robert H Felix was recently appointed to succeed Dr Kolb (THE JOURNAL November 11, p 713) Dr Kolb was born in Galesville Md Feb 20, 1881 and graduated at the University of Maryland School of Medicine, Baltimore, in 1908 He was commissioned an assistant surgeon in the public health service on July 21 1909 and promoted to passed assistant surgeon in 1913 to surgeon in 1921, to senior surgeon in 1930 and to medical director in 1935 Nearly his entire career with the public health service has been in the field of nervous and mental diseases

Addition to Georgia Warm Springs Foundation

The President has approved a grant of \$171,580 to construct and equip an addition to the Georgia Warm Springs Foundation Hospital to provide additional facilities for service men victims in the treatment of poliomyelitis and spinal injuries The Army, Navy and Marine Corps requested the additional bed space at Warm Springs for the treatment of service connected cases For more than a year the Army has shared the hospital's facilities for this purpose The two story and part basement addition will provide room for 86 more patient beds The foundation is to supply \$171,580 of the \$343,159 total cost Twenty-three other communities in thirteen states were allotted additional funds, totaling \$444,205, toward the cost of maintenance and operation of child care and recreational facilities Among these are Baltimore, Evansville Ind., Holyoke Mass, Poughkeepsie, N Y, High Point, N C, Madison, Wis, and Houston, Texas The Orange (Texas) General Hospital will receive an additional \$15,000 to help defray expenses through March 3 1945

LONDON

(From Our Regular Correspondent)

Nov 18 1944

The Government's Compensation Plan for Industrial Injury

In the House of Commons Mr Herbert S Morrison, home secretary, opened a debate on the government's proposal to make workmen's compensation for industrial injury a state service. It would thus be part of the program for social security and national health. The proposal applies to all workers over school age working under a contract of service or apprenticeship. There will not be a special levy on hazardous industries, as proposed in the Beveridge scheme. Persons not in the hazardous industries were fortunate, the secretary felt and would not mind contributing to the bad luck of those in other, more hazardous, industries. Another departure from the Beveridge scheme is flat rates of benefit with supplements for family needs. A workman who loses an arm, leg, eye or other part will get an industrial injury pension no matter what his earnings or his status in industry. Delays due to litigation between workmen and employers would be abolished under the proposed plan, it was stated. All claims would be paid by the government. Compensation would be based on the degree of disablement instead of on loss of earning capacity. The workman would be encouraged to cooperate in his restoration to health and earning capacity without the fear of losing his compensation. The scheme would apply to personal injuries arising out of employment and to specified industrial diseases.

The Suppressive Treatment of Malaria with Mepacrine (Quinacrine)

During the past year the medical services of the allied forces have learned much about the suppressive treatment of malaria with mepacrine. According to the *Army Medical Department Bulletin* mepacrine will not completely prevent malarial infection; there is no true prophylactic effect. But mepacrine has a valuable action in suppressing the clinical manifestations of malaria. This is shown in a reduced number of attacks, lesser severity of attacks which are not prevented and great diminution in mortality. If mepacrine is continued for four to six weeks after risks of exposure to fresh infection have passed, two good effects may be expected: a high proportion of radical cures, especially in malignant tertian malaria, and a substantial diminution in the number of gametocyte carriers. These results have an important bearing on military operations in malarious areas.

In areas where the risk of malaria is slight and mainly due to *Plasmodium vivax* (benign tertian) it has been found that a total weekly dosage of 0.4 Gm. will act as an efficient suppressive. But most of the areas in which our troops have been operating are highly malarious at some season. Therefore the recommended weekly dosage is 0.6 Gm. or preferably 0.7 Gm. Such doses have less effect on mental and physical efficiency than have equivalent amounts of quinine. These doses have been given over periods of a year or more without demonstrable ill effects. While taking the first few doses some may complain of slightly unpleasant side effects, mainly gastrointestinal but under the present system these effects have been negligible and they soon disappear if the treatment is persisted in. True intolerance to suppressive mepacrine so severe as to contraindicate is rare—only to 0.1 to 0.2 per cent at the outside. Observations in the field show that the more strictly and regularly a unit has mepacrine administered, the fewer the attacks of malaria. Benign tertian infections, however, are liable to reveal themselves at a later date. No treatment is known which will prevent this.

Suppressive treatment never justifies relaxation of personal protective measures against the bites of infective mosquitoes. Evidence accumulated in the past year emphasizes that while the medical services can do and have done much to mitigate and remedy the effects of malarial infections serious conditions may still arise, both at the time and at a later date, because of circumstances over which the services have no control. These are created by failure to enforce antimalarial measures in the strictest manner.

Social Adjustment and Venereal Diseases

The Medical Women's Federation has issued an important statement on the relation of venereal diseases to social and personal maladjustments. The statement says that while the war has brought out splendid qualities in our people and many display magnificent courage and devotion yet it is also responsible for an accompanying malaise. Social disorders are associated with failure to practice ideal conduct as well as lack of discipline and personal responsibility. Among the signs of social malaise are (1) lowering of the standards of honesty and consideration for others, (2) an increase in delinquency, including juvenile delinquency, (3) more widespread indulgence in alcohol among young people, (4) lessening of family ties, (5) sexual incontinence, promiscuity, an increase in soliciting and consequent rise in the incidence of venereal diseases and (6) tolerance of a low type of reading matter and public entertainment. An acceptance of materialistic ideals has led to spiritual poverty, the federation states. The sense of insecurity of life, the loss of home background and other dislocations of war have increased confusion. The immediate satisfaction of an impulse is often accepted. The federation believes that continence (apart from marital relations) is the ideal for both sexes if the vitality of the race and the happiness of individuals are to be assured. They condemn the view that incontinence is not detrimental if precautions are taken against disease and pregnancy. Continence is not harmful to either sex, it is stated. For the prevention of venereal diseases and other social disorders the federation puts forward as minimal essentials (1) recognition of the vital importance of home and family life with opportunities for early marriage, (2) training from an early age in moral responsibility and social obligation, (3) religious training, (4) physical training with instruction in the functions hygiene and control of the body, (5) training in the understanding of the emotions, (6) extension of education into adult life, including parentcraft, for both sexes, (7) encouragement of a high standard of literature and entertainment and (8) suitable opportunities for social contacts and recreation.

Training the Blinded Who Have Also Lost Their Hands

St Dunstan's was founded for the training of men blinded in the first world war. It has to face a harder problem in this war. There are fewer blinded so far but blinded men who are also maimed have increased considerably in number. This is due to the greater blast and fragmentation of shells and bombs and to the increase of land mines. The result is that St Dunstan's has to train blind men who have lost their hands for entirely new occupations. It may be difficult to believe that such men can be trained to use a typewriter and similar instruments, but this is being done, thanks largely to research work in which other bodies have cooperated to produce devices to be used or gadgets that are attached to the cuffs of blinded handless men or one handed men. These consist of hooks, pegs and clips with which they can operate not only a typewriter but also an elevator, a telephone switchboard, a wireless relay switchboard and a phonograph.

The blinded with only one hand or part of a hand are also being trained to use lathes and some of the simpler machine tools. For typing, an ingenious keyboard cover has been

devised to assist in selecting and striking the keys. A switch-board has been produced for use in connection with a new postoffice, semiautomatic telephone exchange. Devices evolved for the comfort and convenience of these doubly handicapped people include a cigaret lighter and a striking braille watch.

AUSTRALIA

(From Our Regular Correspondent)

Oct 6 1944

The Future of Medical Practice in Australia

On August 19 every adult in Australia was asked to record his view as to whether or not he was prepared to grant the commonwealth government increased powers for five postwar years in a wide variety of fields, including "national health in cooperation with the states or any of them." The count of votes has now been completed and the final answer was a definite negative. The figures were 1,963,400 in the affirmative, 2,305,418 in the negative and 56,333 undecided. Because of this defeat in the referendum, two of the plans for the extension of commonwealth social services are in danger of collapse on constitutional grounds. The first scheme is that to provide free medicine, which was provided for in legislation passed early this year but is not yet in operation. In the financial budget for the forthcoming year, provision has been made for this scheme to become operable in January 1945. There has been a failure to reach a general agreement with the medical profession as regards its cooperation in this free medicine scheme. The second proposal was the national medical services scheme, which was promised when the national welfare fund was created last year. There is no provision in the constitution which authorizes the commonwealth to undertake this service or even such social services as have been operating for many years, such as the payment of maternity benefits. One of the difficulties of both the free medicine scheme and the national medical services scheme is that they both conflict sharply with the work and interest of the friendly societies and at the same time revolutionize the established practice of retail chemists and doctors. Any of these groups, or an individual from any group, could take action to have the legislation declared unconstitutional, and it is recognized in commonwealth quarters that any such action would probably be successful. The arrangement made at the premiers' conference for a commonwealth subsidy to provide free treatment in all public hospital beds in Australia is unconstitutional. The commonwealth, however, has a general constitutional power to make grants to the state, and the free hospital scheme legislation could doubtless be so framed as to depend on this power and thus survive a challenge. It is unlikely that the state governments will give the commonwealth government extended power to deal with health services. Alternatively, the states themselves may embark on separate schemes to be fused later into an Australianwide service.

Nursing Reform

The first report of the committee for reorganization of the nursing profession has now been published. The chairman of the committee is Hon C. A. Kelly, M.L.A., minister for health in New South Wales. The primary reason for seeking to improve the status and training of nurses, as well as nursing conditions, is that for some time it has been apparent that not so many women have been volunteering for training as nurses, and even among those who complete their course many seek more lucrative employment elsewhere. Main questions for review by the committee were increased remuneration, providing for shorter hours and permitting nurses to start training at 17 instead of 18 years of age. The committee appointed three subcommittees to deal with the various aspects of the problem under the following headings: recruitment—to consider the establishment of a central recruitment bureau for a

publicity campaign, conditions—to consider the allotment of better salaries, better living conditions, improved diet and lay help for domestic duties in hospitals, training—to improve the standing and status of the nursing profession from preliminary training through postgraduate to higher specialized positions. The committee is opposed to reducing the training period from four years to three years but recommends that girls be allowed to enter a preliminary training school at the age of 17 and serve a twelve months course in that school, that year to be counted as one of the four year course. It is recommended that trainees be allowed £130 a year, including board and lodging. The term "student nurse" instead of "probationer" should be used in all training schools, the committee also suggests. The establishment of a college of nursing which will control the preliminary training schools is recommended. This will be a body constituted by the government, with representatives of the nursing profession, university, medical profession and other interested groups. Postgraduate courses for trained nurses wishing to qualify as hospital and ward administrators, and Sister Tutors should be inaugurated in conjunction with university and technical college, it is proposed. Salaries for nurses should be increased, and an allowance of £26 per annum, subject to a "means" test, be granted to girls between the ages of 15 and 17 years who wish to take up nursing, to enable them to stay at school and undergo training for nursing. Conditions which are often unfavorable to nurses need to be reviewed, the committee believes. These are working hours, leaves of absence, accommodations, social life, diet, fitness of seniors to handle staff, superannuation, volume of work and uniform. The educational standard of those taking up nursing should remain as at present, while the shortage of recruits persists, but eventually it should be raised, the committee states. All training schools should have the services available of Sister Tutors—one Sister Tutor to every fifty or sixty student nurses. Specialist work should be encouraged. The committee considers that the title "Sister" should apply to every graduate nurse and the term "general nurse" or "staff nurse" be abolished. This now applies throughout the army and air force nursing services.

High Cost of Social Services in Australia

Ten years ago the total budget of the commonwealth of Australia was £71,000,000, and in 1939, when some war expenditure was met, it was £101,000,000. In the future it is estimated that social services alone will cost the commonwealth £100,000,000. This is made up as follows: invalid and old age pensions, child endowment and widows' pensions, £36,750,000, maternity allowances, funeral allowances, pharmaceutical benefits, sickness, unemployment and hospital benefits, £19,610,000, provision of medical and hospital benefits, £20,000,000, present repatriation costs, £10,400,000, and future repatriation commitments, £10,000,000. With a population of 7,000,000, this will represent an annual cost of £14 per capita.

Marriages

CHARLES C. HARROLD JR., Macon, Ga., to Lieut. Paulette Marguerite Devinck in Vesoul, France, recently.

JOHN EDWARD HUGHES, New York, to Miss Lucille Romona Hoffmann of Brooklyn, October 21.

JOHN CLAYTON O'DELL JR., to Miss Glory Sims Mott, both of Jacksonville, Fla., September 29.

WILLIAM H. JACOBSON, Canton, Ohio, to Miss Elaine P. Rhein of Brooklyn, October 21.

ROBERT G. ROSSER JR., Vass, N. C., to Miss Clara Holcombe of Weaverville, October 11.

PAUL A. MANKOVICH, Latrobe, Pa., to Miss Irene Petrick of Farrell, September 7.

FRANK J. IVERSEN, Omaha, to Miss Marcella O'Connor of San Francisco in April.

Deaths

William Alvin Bryan, Norwich, Conn., George Washington University School of Medicine, Washington, D. C., 1908, specialist certified by the American Board of Psychiatry and Neurology, Inc. member of the American Medical Association, American Psychiatric Association Massachusetts Psychiatric Society and the New England Society of Psychiatry, past president of the Worcester District Medical Society and Massachusetts Association for Occupational Therapy formerly member of the board of managers of the National Association for Occupational Therapy at one time worked with the U. S. Public Health Service served as chairman of the Massachusetts Board of Nursing Registration for many years lecturer in social administration Boston University School of Religious Education formerly on the staffs of the Cherokee State Hospital, Cherokee Iowa, Psychopathic Hospital Boston and Danvers State Hospital, Hathorne Mass. assistant to the commissioner Massachusetts Department of Mental Diseases Boston 1920-1921, for many years superintendent of the Worcester State Hospital, Worcester, Mass. since 1940 superintendent of the Norwich State Hospital where he also maintained his residence and where he died November 7, aged 60 of broncho pneumonia.

Henry S. Cole ♂ Lieutenant Colonel U. S. Army retired Clearwater, Fla. Chicago Homeopathic Medical College, 1902, U. S. Army Medical School, 1925, Medical Field Service School, Carlisle Barracks, 1925 completing an advanced course in 1936 veteran of the Spanish-American War and World War I, served as captain of infantry in the Michigan National Guard instructor in medical officers' training camp at Fort Riley Kansas 1917-1918, entered the medical corps of the U. S. Army as a captain in 1920 promoted to major in 1929 and retired with the rank of lieutenant colonel in 1937 for disability incurred in line of duty member of the Association of Military Surgeons of the United States, for four terms mayor of Owosso and Whitehall Mich. served as health officer for many years and as chairman of the county Republican conventions, organized the Pinellas County medical defense in 1941, serving as a member of the draft board of Pinellas County since 1942 active in the Kiwanis Club died in the AAF Regional Station Hospital Drew Field November 6 aged 65, of hypertension and coronary heart disease.

William Wesley Wright, Utica, N. Y. University of Michigan Department of Medicine and Surgery Ann Arbor 1904 formerly senior assistant physician at the Psychiatric Institute New York served as clinical instructor in medicine in the departments of psychopathology and psychiatry at Cornell University Medical College and later chief of the Cornell Clinic, New York member of the American Medical Association and the American Psychiatric Association past president of the Utica Academy of Medicine served as acting clinical director of the Manhattan State Hospital in New York and as first assistant physician at the Buffalo State Hospital, Buffalo at one time superintendent of the Pilgrim State Hospital Brentwood formerly assistant superintendent of the Utica State Hospital became medical superintendent of the Marcy State Hospital Marcy in July 1931, when it separated from the Utica State Hospital, retiring in 1943 on the staffs of the Faxon Hospital and St. Elizabeth Hospital where he died October 28, aged 71 of cerebral hemorrhage.

Samuel Clifton Baldwin ♂ Salt Lake City University of Louisville Department of Medicine Louisville, Ky. 1884 specialist certified by the American Board of Orthopedic Surgery Inc. member of the House of Delegates of the American Medical Association 1904 1905 and 1908, member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons past president of the Utah State Medical Association lieutenant colonel in charge of the army orthopedic department during World War I, colonel, medical reserve corps U. S. Army, not on active duty for many years chief of the Primary Children's Hospital on the staffs of the Dr. W. H. Groves Latter-Day Saints Hospital Holy Cross Hospital and the Salt Lake County General Hospital consulting surgeon at the Utah State Hospital, Provo recently received the honorary degree of doctor of science from the University of Utah, where he had been a member of the board of regents died October 19, aged 89 of coronary heart disease.

John Leeming ♂ Chicago, Victoria University Medical Department, Coburg, Ont., Canada 1886 L.R.C.P., London England, 1886, also a lawyer Second Vice President of the

American Medical Association, 1916-1917 formerly connected with Northwestern University Medical School as lecturer and professor of materia medica, served as professor of medical jurisprudence and lecturer at the Kent College of Law, formerly attending surgeon at the Chicago Baptist and Cook County hospitals, retired medical counsel for the Chicago Surface Lines, died in the Illinois Central Hospital November 4, aged 85 of cerebral hemorrhage.

Fletcher Gladstone Asbill ♂ Ridge Spring, S. C. University of Maryland School of Medicine, Baltimore 1894, vice president of the Ridge Banking Company, died in the Columbia Hospital, Columbia, November 5, aged 76, of carcinoma of the urinary bladder.

George James Aste ♂ Chicago, Chicago College of Medicine and Surgery, 1908, formerly assistant professor of operative surgery at the Chicago Polyclinic died November 14, aged 66, of carcinoma of the descending colon and rectum, with general metastasis.

James Knox Polk Blackburn, Pulaski, Tenn., Vanderbilt University School of Medicine, Nashville, 1893, president and formerly vice president and member of the state board of medical examiners, member of the state basic science board, city and county health officer, served during World War I, member of the American Medical Association and past president of the Middle Tennessee Medical Society, died October 31, aged 71, of heart disease.

Thomas Francis Brennan ♂ Ness City, Kan., Creighton University School of Medicine, Omaha, 1929, president of the Rush-Ness Counties Medical Society served an internship at the Creighton Memorial St. Joseph's Hospital, Omaha, died in Hays August 26 aged 39 of cerebral hemorrhage.

Albert A. Brooks, Orrville, Ohio, Homeopathic Hospital College, Cleveland, 1882 died October 24, aged 86, of broncho pneumonia.

Myron Ernest Carmer, Lyons, N. Y. University of Vermont College of Medicine, Burlington 1885 member of the American Medical Association died November 6, aged 90, of myocarditis.

Harry Elmore Clark ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1888 president of the Sheraden Bank, served as vice president of the University of Pittsburgh Fifty Year Alumni Club died October 23 aged 82, of coronary sclerosis.

Leonard Hamilton Clark, Mancos Colo. Colorado School of Medicine Boulder, 1894, died October 14 aged 82, of endocarditis and senility.

Emmett Addis Corbin, Eaton Colo., College of Physicians and Surgeons, Baltimore, 1907, served during World War I, formerly on the staff of the Greeley Hospital, Greeley, died October 5, aged 61, of pulmonary embolism following an operation for cancer.

Phillip G. Cowing, Evansville, Minn. (licensed in Minn. 1894) died in Fergus Falls August 21 aged 72 of myocarditis.

Matthew F. Creaven, Pittsburgh, College of Physicians and Surgeons Baltimore 1891 died October 21, aged 80 of chronic nephritis and general arteriosclerosis.

Harvey Thomas Cuming ♂ Pace Miss. University of Tennessee Medical Department Nashville, 1899, served overseas during World War I died September 29, aged 67, of hypertensive heart disease.

Dowdal Henry Davis ♂ Independence Kan., Howard University College of Medicine Washington D. C., 1906 died September 28 aged 61.

Charles G. Dean, Greeley, Colo. University of Louisville (Ky.) Medical Department 1893, died September 13, aged 77 of arteriosclerosis.

James L. De Foe, Chesterfield, Mo. Missouri Medical College St. Louis 1891 died in the Missouri Baptist Hospital St. Louis, September 28, aged 79, of lobar pneumonia.

Robert Samuel Edwards, Cedar Vale Kan., Bennett Medical College, Chicago 1910 member of the American Medical Association died September 5, aged 78, of cardiovascular disease.

William Henry Ewin, Portland Ore., University Medical College of Kansas City Mo., 1891 died September 24 aged 76 of cerebral thrombosis.

George Lewis Fischer, Buffalo University of Buffalo School of Medicine, 1903, member of the American Medical Association, died October 12 aged 66 of cerebral hemorrhage and arteriosclerosis.

Joseph Allen Fisher * Metropolis Ill., St. Louis University School of Medicine, 1905 founder and owner of the Fisher Hospital in 1942 had been chosen president of the Southern Illinois Medical Association died November 1 aged 63 of coronary thrombosis

Frank Nathan Gaggin, Chicago Reliance Medical College Chicago, 1909 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1910, member of the American Medical Association past president and for many years a member of the staff of the Norwegian American Hospital, died October 27 aged 74 of chronic myocarditis

Eugene A. Gilbert * Chattanooga Tenn., Vanderbilt University School of Medicine Nashville 1913 member of the American Society of Anesthetists past president of the Chattanooga and Hamilton County Medical Society on the staffs of the Pine Breeze Sanatorium and the Baroness Erlanger Hospital died in Sarasota Fla. October 16 aged 55 of heart disease

Alexander Liddell Gillars Philadelphia Jefferson Medical College of Philadelphia, 1888 member of the American Medical Association served during World War I formerly a resident of Pottsville Pa. where he had been on the staffs of the Pottsville Hospital deputy coroner member of the school board and physician for the Schuylkill County Jail died October 7 aged 78, of cardiovascular disease and prostatitis

Robert Cunningham Hanna, Varion Ala. Hospital College of Medicine Louisville 1902 member of the American Medical Association died in the Goldsby King Memorial Hospital, Salem, October 16, aged 66, of carcinoma of the liver

Charles Henry Hayton * Los Angeles George Washington University School of Medicine Washington D. C., 1911 professor emeritus of otolaryngology at the College of Medical Evangelists, specialist certified by the American Board of Otolaryngology fellow of the American College of Surgeons on the staffs of the California and White Memorial hospitals died October 9, aged 75 of heart disease

Cecil Theodore Heidel, Evanston Ill. Northwestern University Medical School, Chicago 1912 formerly clinical instructor in pediatrics at Rush Medical College Chicago, died November 14, aged 62, of cerebral hemorrhage

William Cephas Herman * Cincinnati Miami Medical College Cincinnati 1902 also a pharmacist died October 24, aged 71 of carcinoma

William Henry Hogue, Marietta, Ohio, University of Louisville (Ky.) Medical Department 1894 died September 21, aged 75, of chronic myocarditis

John H. Lapointe, Meriden Conn. School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal 1892 member of the American Medical Association formerly police commissioner, on the staff of the Meriden Hospital died September 16 aged 78, of coronary thrombosis

Jarl F. Lemstrom, Minneapolis University of Minnesota College of Medicine and Surgery, Minneapolis, 1907 formerly assistant in embryology at his alma mater died September 24, aged 63 of carcinoma of the pancreas

Joseph Moses Lindenbaum, Chicago Rush Medical College Chicago, 1923 died October 25 aged 46 of melanoma

William A. Lurie, New Orleans Rush Medical College Chicago, 1903 member of the American Medical Association formerly clinical assistant in surgery at his alma mater died in the Touro Infirmary September 24 aged 63 of carcinoma of the pancreas

Thomas Edward MacKedon, Milwaukee Marquette University School of Medicine Milwaukee 1913 served overseas during World War I, on the staffs of the Deconess and Misericordia hospitals died in the Veterans Administration Hospital, October 3 aged 57 of cerebral hemorrhage and essential arterial hypertension

Angus Malcolm McAuley * Bvhalia, Miss. Memphis (Tenn.) Hospital Medical College 1904 examining physician for the draft board during World Wars I and II for many years county health officer died November 26 aged 66 of cerebral hemorrhage and arterial hypertension

Harvey Benjamin McCrory, Munising Mich. Detroit Homeopathic College 1909 served during World War I formerly physician of Saginaw County died in Grand Rapids October 1, aged 59 of interstitial nephritis and diabetes mellitus

William Edward Merrick * Cleveland, University of Wooster Medical Department Cleveland, 1908, for many years physician for the W. S. Tyler Company, on the staffs of St.

Ann's Hospital, St. John's Hospital and St. Vincent Charity Hospital where he died October 11 aged 60 of cerebral hemorrhage

James Mitchell, Gladstone, Mich. Queen's University Faculty of Medicine Kingston Ont. Canada 1899 member of the American Medical Association city health officer served as president and for many years as a member of the board of education died October 20 aged 74, of nephritis

Walter Willard Overfield, Forrester Ill. Rush Medical College, Chicago, 1890, for many years president of the Commercial State Bank died October 1 aged 76 of heart disease

Ivan Bryan Parker, Hill City Kan. University Medical College of Kansas City Mo. 1894 member of the American Medical Association died October 4, aged 73 of hypertension

Henry Vincent Pennington * London, Ky. Tennessee Medical College Knoxville 1891 Hospital College of Medicine Louisville Ky., 1899 Jefferson Medical College of Philadelphia 1900 served as president of the Laurel County Medical Society medical director and owner of the Pennington General Hospital where he died October 15 aged 74 of cerebral hemorrhage and diabetes mellitus

John Charles Peters, Amityville N. Y. New York Homeopathic Medical College and Flower Hospital New York 1931, member of the American Medical Association served an internship at the Flushing Hospital and Dispensary Flushing N. Y. and as resident physician at the Kingsway Hospital in Brooklyn, on the staffs of the Southside Hospital Bay Shore Nassau Suffolk General Hospital, Copiague and the Brunswick Home died October 6 aged 36 of coronary occlusion

Joel C. Poindexter, Imboden Ark. Hospital College of Medicine, Louisville Ky., 1896 died October 4, aged 79, of cerebral hemorrhage

Michael L. Porvaznik * Duquesne, Pa. University of Pittsburgh School of Medicine 1928 president of the Duquesne Medical Society served an internship at the Western Pennsylvania Hospital Pittsburgh on the courtesy staff of the McKeesport Hospital, McKeesport, died October 11 aged 40 of pulmonary tuberculosis

Wyeth Elliott Ray, Pawling, N. Y. Yale University School of Medicine New Haven, Conn., 1898, formerly medical director of the Travelers' Life and the Germania Life Insurance companies, died October 25 aged 66, of coronary thrombosis

James Powell Riffe, Covington, Ky. Medical College of Ohio, Cincinnati, 1894 since 1933 coroner of Kenton County formerly health officer of Covington on the staffs of St. Elizabeth and William Booth Memorial hospitals served as chairman of the Kenton County Chapter of the American Red Cross, as president of the Kenton County Tuberculosis League Commission and as secretary of the Campbell-Kenton Counties Medical Milk Commission died October 20 aged 72 of carcinoma

Arthur Garfield Ringer * Cambridge Ohio Ohio Medical University Columbus 1904 died in the White Cross Hospital Columbus, September 30 aged 63 of congestive heart failure and acute nephritis

Frank Henry Sargent * Pittsfield, N. H. Dartmouth Medical School Hanover 1890 served on the school board and in 1929 member of the New Hampshire legislature, at one time physician in charge of Sargent Hall formerly president and later trustee of the Pittsfield Savings Bank died July 11 aged 83, of hypostatic pneumonia and intracranial hemorrhage due to a fall

Theodore H. Schreuder, Chicago Rush Medical College Chicago 1891 died in the Norwood Park Norwegian Old People's Home October 7 aged 84 of myocarditis and arterio sclerosis

Herbert Emerson Smead, Toledo Ohio, Western Reserve University Medical Department Cleveland 1897 at one time associate professor of pediatrics at the Toledo Medical College past president of the Academy of Medicine of Toledo and Lucas County formerly chief of staff of the Toledo Hospital, where he died October 21 aged 71 of bilateral bronchopneumonia

Frank Clinton Smith, Geneva Ohio, the Hahnemann Medical College and Hospital Chicago 1893 member of the American Medical Association member of the Ashtabula County Board of Health formerly health officer and secretary-treasurer of the board of education in Geneva, member of the Rotary Club anesthetist at the Community Hospital, where he died October 12 aged 77, of coronary thrombosis

Joseph Benjamin Smith * Braddock, Pa., Medical Department of the Western University of Pennsylvania, Pittsburgh,

1907, on the staff of the Braddock General Hospital died October 16, aged 64, of coronary thrombosis

Charles-William Snyder, Louisville, Ky, Yale University School of Medicine New Haven, Conn, 1900, medical director of the Domestic Life and Accident Insurance Company, chairman of the board of directors of the Red Cross Hospital, died October 11, aged 74, of hypertensive heart disease

Frederick George Speidel Ⓢ Louisville, Ky, University of Louisville School of Medicine, 1917, assistant clinical professor of pharmacology at his alma mater, fellow of the American College of Physicians, member of the Southern Medical Association specialist certified by the American Board of Internal Medicine, served in the U S Navy during World War I on the staffs of the Norton Memorial Infirmary, Kentucky Baptist St Anthony's and Kosair Crippled Children hospitals died October 15, aged 55 of coronary occlusion

Solomon Ellis Spratt, Mount Sterling Ky Kentucky School of Medicine, Louisville, 1900 died in the Good Samaritan Hospital, Lexington, October 18, aged 75, of heart disease

Enoch Lafayette Stamey, Greensboro, N C, Atlanta Medical College 1895 died October 17 aged 84 of cardiovascular renal disease

I, formerly owner and medical director of the West Side Hospital, died in St Francis Hospital September 27, aged 65, of carcinoma of the cecum

Burtrum L Ware, Fort Smith, Ark University of Arkansas School of Medicine, Little Rock, 1909, member of the American Medical Association, past president of the Sebastian County Medical Society, served as vice president of the Farmers Bank of Greenwood, on the staffs of the Sparks Memorial and St Edward's Mercy hospitals died October 11, aged 61 of heart disease

Minerva Porter Wertz, Spencer, Iowa, State University of Iowa College of Medicine, Iowa City, 1893, died September 13 aged 73, of myocarditis

John Harrison Wood, Georgetown, Miss, Memphis Hospital Medical College Memphis, Tenn, 1904, died October 2 aged 74, of heart disease

Eugene Wynne, Brooklyn, Long Island College Hospital, Brooklyn, 1908, member of the American Medical Association head physician of the Bethlehem Steel Company plant served on the staffs of the Norwegian Hospital, Samaritan Hospital and the Methodist Hospital, where he died October 21, aged 60 of heart disease

William McHenry Swickard Ⓢ Charleston, Ill Rush Medical College, Chicago 1926, on the staff of the M A Montgomery Memorial Hospital, died October 15, aged 46 of adenocarcinoma

Colmore Hasty Tate, Chicago, Chicago College of Medicine and Surgery, 1913, died October 5, aged 56, of coronary thrombosis

David Thomas Ⓢ Lorain Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912 member of the board of censors, past president and vice president of the Lorain County Medical Society, trustee of the Pleasant View Sanatorium, chief of the obstetric department of St Joseph's Hospital, a lieutenant in the medical corps of the U S Army during World War I died October 19, aged 58 of cardiac failure and carcinoma of the sigmoid

Hubert Dale Joseph Thomas, Dallas Texas Baylor University College of Medicine, Dallas, 1943, served an internship and residency in medicine at the Wichita Falls Clinic Hospital, Wichita Falls, died in a local hospital September 26, aged 31

Thomas Raymond Usher Ⓢ Maplewood, Mo St Louis University School of Medicine, 1932, formerly an intern, resident in surgery and superintendent of St Louis County Hospital Clayton served on the staffs of Deaconess Hospital, St Mary's Hospital and the Missouri Baptist Hospital St Louis, where he died September 30, aged 40 of injuries received when his automobile collided with a street car

Benjamin Van Campen, Olean, N Y University of Buffalo School of Medicine 1908 served during World War

Arthur John Zimlick Philadelphia, Washington University School of Medicine, St Louis 1895 member of the American Medical Association, served during World War I died in St Joseph's Hospital September 2, aged 70, of arteriosclerotic heart disease

KILLED IN ACTION

William E McClain Jr, Seattle Creighton University School of Medicine, Omaha, 1938, served an internship and residency in surgery at the King County Hospital, commissioned a first lieutenant in the medical corps, Army of the United States, on July 7, 1942 later promoted to captain, a flight surgeon, killed in action in the European area June 19, aged 31

Zephaniah Branch Weingart Jr, Lecompte, La, Tulane University of Louisiana School of Medicine, New Orleans, 1942 served an internship and residency at the Charity Hospital in New Orleans, commissioned a first lieutenant in the medical corps, Army of the United States, on July 7 1942, later promoted to captain, killed in action in the European area July 13, aged 27

Isadore Marvin Silverman, Brooklyn Creighton University School of Medicine, Omaha, 1936 served an internship at the Hospital for Joint Diseases in New York commissioned a first lieutenant in the medical corps, Army of the United States on July 3, 1942 later promoted to captain, killed in action in France, August 26 aged 32

Council on Medical Education and Hospitals

GRADUATE CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning graduate continuation courses for practicing physicians available in various centers is published semiannually. The following list consists

of courses beginning during the period January 1 through June 30, 1945. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the institution listed.

Institutions offering continuation courses are invited to announce such courses in these semiannual lists compiled by the Council on Medical Education and Hospitals.

TABLE OF CONTENTS

Subject	Page	Subject	Page	Subject	Page
Allergy	1103	Fractures	1103	Otorhinolaryngology	1109

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Hydrocele Allegedly Resulting from Blow to Leg—In the course of his employment on Sept 8 1939 Chambers was struck on the right leg below the knee by a heavy iron beam. He was given first aid and continued working. A few days later his leg became infected and on September 18 he was sent to a physician who then observed an infected area about an inch or an inch and a half wide and 3 inches long. The workman was in bed for a week thereafter did not return to work for another week and so far as the infected leg was concerned was thereafter able to work. The infected leg however did not heal and treatments by his attending physician were continued. Finally sulfamidamide was administered internally, and the infection cleared up sometime in January 1940. The employer's insurance carrier paid the workman compensation under the workmen's compensation act of Nebraska for two weeks and paid Chambers' physician for the services he had rendered up to that time. Sometime later a hydrocele developed on the left side and he instituted proceedings under the Nebraska Workmen's Compensation Act claiming the hydrocele resulted from the blow. The lower tribunals denied him recovery and he then appealed to the Supreme Court of Nebraska.

The sole question to be determined said the Supreme Court, is whether or not the evidence adduced in the lower courts was sufficient to show a causal relation between the injury to the right leg suffered in the course of employment and the subsequent hydrocele that developed in the region of the left testicle. In arriving at a determination as to the presence or nonpresence of such a causal relation the following rules of law must be kept in mind: first the burden of proof is on the claimant to establish by a preponderance of the evidence that the personal injury sustained was sustained from an accident arising out of and in the course of employment; secondly, a compensation award cannot be based on possibilities or probabilities but must be based on sufficient evidence that the claimant incurred a disability arising out of and in the course of his employment. The court then went on to test the evidence adduced before the lower courts in the light of the rules

of law just stated. The plaintiff, the court continued, testified that the hydrocele first appeared three days after he "went to bed" Sept 18, 1939, about two weeks after the industrial accident, that he called it to his physician's attention, that the physician first treated it from four to six weeks after it appeared, that since that time it has been drained once every six to eight weeks, and that he has never had any venereal disease and no infection in his system other than that resulting from the leg injury. The workman's physician, a general practitioner, testified that the workman had a severe traumatic ulceration at the point of the bruise caused by the industrial accident that his patient's leg was swollen to the groin, and that there was a glandular involvement on both sides. This physician did not fix a time when the hydrocele appeared but stated that it "was probably developing" on Sept 21, 1939 but that he was not sure it was a hydrocele for two or three weeks thereafter. The physician believed that the industrial accident caused the injury which was followed by infection, that the infection spread to the groin, finally reaching the left testicle and settled there causing the hydrocele, and that there was a direct causal connection between the wound and the hydrocele. He admitted however that he had never encountered in his practice nor had he read of, a similar result from such an infection. On behalf of the employer and its insurance carrier "a specialist engaged in both teaching and practice testified that he had examined the plaintiff that an infection or trauma of the scrotum or contents or circulatory disturbances might cause an acute hydrocele that the cause of a chronic hydrocele is not known that he had never heard nor read of a chronic hydrocele being caused by a leg infection, such as the workman in this case had that an infection from the right leg might "by a wild stretch of the imagination involve the right testicle, but that he had never seen nor heard of such a case, and that had such a case occurred it would have been reported in the medical literature. He gave it as his opinion that the hydrocele was purely "coincidental" and that there was no connection between the industrial accident in this case and the hydrocele.

The following facts continued the court must be considered in this connection. The workman's physician, while having definite knowledge of the hydrocele a few weeks after the infection, made no mention of that fact in his reports to the insurance carrier submitted during the period of treatment for the leg. While he testified that he was treating the hydrocele during that period he made no charge for that treatment, as such during the period from September 1939 to January 1940. His bill for services submitted to the carrier and paid by it stated that it was for services to the infected leg. While he testified that he prescribed the use of a suspensory the bill of drugs submitted to and paid by the insurance carrier made no mention of that device. The physician prepared a second statement for services rendered from March 1940 to May 31 1941. The testimony shows that while there was an aspiration performed on March 11 1940 it was described in the statement rendered to the insurance company as an "office call." The first entry on the charge account which has reference to the hydrocele was made on Oct 1 1940. The employer and his insurance carrier were not then notified of the disability and so far as can be discovered from the record the defendants were not advised of the claim that the hydrocele resulted from the infection until the present court proceedings were instituted.

It further appears continued the court, from the testimony of both the physician called by the workman and the physician called by the employer and his insurance carrier that the etiology of a chronic hydrocele such as the workman has, is not known to the medical profession and that there are no cases in medical literature showing that a hydrocele has been caused by an infection such as the workman had. Injuries of this kind with resulting infections occur quite commonly to men. If there was a cause and effect relationship between such an infection and a hydrocele it seems to us that the medical profession would ere now have discovered that fact. The most that can be said, concluded the court, for the evidence adduced by the workman is that it indicates that there might possibly be a connection between the industrial accident and the hydrocele. That is not sufficient to warrant a recovery for the workman.

•The court accordingly denied compensation—*Chambers v. Bilhorn, Borcer & Peters* 16 N W (2d) 173 (Neb 1944)

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Differential Diagnosis of Glycosuria—John suggests the following test for diagnosis of diabetic glycosuria. After sugar has been discovered in the urine, the patient should eat a heavy carbohydrate lunch at 11:30 a.m. The blood sugar should be determined two and a half hours from this time. About 2 cc of blood is adequate for this purpose. If the blood sugar is below 120 mg per hundred cubic centimeters the patient is non-diabetic. If the blood sugar is above 120 he is probably diabetic. If it is well above 120, say 200 or more a frank diabetes exists. If it is 126 or 136, one needs to go into the problem further and do a glucose tolerance test the next morning. Non-diabetic glycosuria is not a precursor of diabetes. The renal threshold in a nondiabetic glycosuria is usually low. It varies on the ascent and descent of the curve, being higher on the former and lower on the latter. On the finding of glycosuria, a diagnosis should be arrived at within twenty-four hours. This will eliminate the possibility of self-imposed dietary restrictions which distort the glucose tolerance curve (toward the diabetic side) and thus give false information. There is no treatment for nondiabetic glycosuria and none is needed.

Salmonella Enterocolitis in Infants and Children—Neter and Clark studied 21 bacteriologically proved cases of Salmonella enterocolitis at the Children's Hospital of Buffalo. The ages of the patients ranged from 11 days to 12 years. Eighteen were less than 2 years and 10 less than 3 months of age. One of the cases represents an unusual instance of Salmonella thompson enterocolitis. Eleven cases of enterocolitis were due to Salmonella typhi murium. Several of the patients were admitted because of this condition, while others developed the diarrheal disorder during hospitalization for unrelated illnesses. Added precautions checked the outbreak. In several cases Salmonella enterocolitis developed during or following other diseases namely meningococcal meningitis streptococcal bacteremia and bronchopneumonia. Eighteen patients recovered and 3 died. Fourteen of the 21 patients including 1 who died, were treated with sulfonamides. No definite statement can be made regarding beneficial effects resulting from this treatment. In several instances chemotherapy with sulfonamides, including the use of succinylsulfathiazole, failed to eradicate the paratyphoid bacilli from the intestinal tract.

Rheumatic Fever in Cincinnati—The Wedums recently completed an investigation of persons hospitalized for rheumatic conditions in Cincinnati for the eleven year period 1930 to 1940. Out of a total of 2,178 cases 583 were subjected to a socioeconomic analysis. Data obtained are recorded in maps showing distribution by city census tracts of cases of rheumatic fever admitted to Cincinnati hospitals during 1930 to 1940 and also the annual incidence of hospitalized rheumatic fever per hundred thousand of population in each census tract in relation to rentals, crowding, density of population and Negro population. The survey emphasizes the importance of poverty and crowding in the genesis of rheumatic fever.

Complement Fixation Test of Lymphogranuloma Venereum—According to Beeson and Miller immunologic evidence of infection with the virus of lymphogranuloma venereum is frequently encountered in persons who show no sign of the clinical disease. The present report is an analysis of a series of complement fixation tests done on clinic patients at Grady Hospital, Atlanta. Complement fixation tests for lymphogranuloma venereum were done on 879 patients. Approximately 40 per cent of adult Negroes and 12 per cent of adult white persons gave positive reactions. There were only 6 positive reactions among 116 Negro children under the age of 14 years, and only 1 positive reaction among 58 white children in the same age group. A sharp rise in incidence occurred after the age of 14 years. This is believed to be due to acquired venereal infection. The incidence of positive reactions was approximately the same in all age groups beyond the fourth decade. This persistence of an immune reaction in age groups with less sexual contacts suggests that the virus persists in the body, providing continued antigenic stimulus. Comparisons were made in newborn Negro infants and their mothers. It was found that immediately after birth the reaction in the infant's serum is the same as that of the mother. Nine infants who had given positive reactions were retested two to four months later, they had all become negative. A positive test at birth seems due to the passive transfer of antibodies from the mother. The error introduced by the fact that infection with other members of the lymphogranuloma-psittacosis group of viruses will give rise to a positive complement fixation test for lymphogranuloma venereum cannot be assessed. It is not likely that the prevalence of infection by the other agents in this group is sufficient to distort greatly the picture of the prevalence of lymphogranuloma venereum.

Types of Hemolytic Streptococci in Same Household—During a twenty-six month period throat cultures on 824 of 1,048 scarlet fever admissions to a contagious disease hospital were examined by Foley and his co-workers for hemolytic streptococci. Cultural and serologic data were available for 57.1 per cent of all scarlet fever admissions during this period. Of the cases studied 134 occurred as multiple infections in 55 families. There were seven different serologic types of hemolytic streptococci involved in these 55 households, and, as would be expected, the type isolated from multiple cases in a given household was the same in all instances. Family outbreaks in general probably are single source outbreaks caused by a single serologic type of hemolytic streptococci, whereas scarlet fever in a sizable community appears to be caused by multiple types, perhaps the

result of the introduction of a number of strains from different sources. It may be postulated that endemic scarlet fever is composed of numerous outbreaks occurring in basic units of population such as the family, the whole of which gives the varied type pattern characteristic of the disease in its endemic form. Epidemiology of endemic scarlet fever is complicated by the unavoidable multiplicity of human contacts, but in those circumstances in which the movement of a particular serologic type of hemolytic streptococci can be followed, person to person spread can be demonstrated.

Serologic Studies of Bullis Fever—Livesay and Pollard studied Bullis fever for serologic identification or differentiation from some of the known rickettsial diseases. The majority of the cases occurred in a group of men stationed at Camp Bullis, Texas, during a high degree of insect infestation of the area. Two months after the outbreak 261 serums were collected from those who had had Bullis fever. All presented a history of tick and chigger bites, sudden onset of illness, severe headache, lymphadenopathy and leukopenia. Deer, rabbits, raccoons and 1 armadillo from the Camp Bullis area were shot, and serum specimens were collected for examination. Serum specimens were tested for Weil-Felix agglutination reaction and by the complement fixation reaction for endemic typhus, American Q fever and Bullis fever. One hundred and ninety-two human and 50 animal specimens were examined. The Bullis fever antigen was prepared by triturating with sand the enlarged infected spleens of mice and adding approximately 20 per cent by volume sterile isotonic solution of sodium chloride. The specificity of the antigen was supported by the negative reactions with serum from cases of endemic typhus fever, Q fever, Rocky Mountain spotted fever, scrub typhus and normal serums. The positive serologic tests for Bullis fever in 4 of 40 deer and 2 of 7 rabbits might mean that these animals constitute the reservoir species. The authors tabulate 50 random cases all of which gave negative Weil-Felix reactions and were negative for endemic typhus. Two cases were positive for American Q fever. Forty seven gave positive results for Bullis fever. Of the total number of 192 human specimens 76 per cent gave positive complement fixation for Bullis fever. The authors stress the following points: 1. The Bullis fever syndrome is not characterized by a significant Proteus OX-19, OX-K or OX-2 agglutination reaction. 2. There does not appear to be any serologic relationship between the rickettsia-like agent of Bullis fever and the rickettsia of American Q fever by the complement fixation test. 3. From the results obtained there does appear to be some significant serologic relationship between the agent isolated from a human case of Bullis fever and the serums of convalescent cases.

Early Filariasis in American Troops—King studied 268 American troops who had lived an average of four months in Pacific islands and who presented symptoms and signs believed to be due to filariasis. Attention was first drawn to the possibility of filariasis by a patient with epididymitis who later developed lymphangitis of one arm. Biopsy of a lymph node of another patient showed adult filariae in the subcapsular sinuses. Similar cases were observed by other investigators among these troops as early as five months after exposure. The earliest onset was three months after arrival at the island. The syndromes observed fall into three categories: lymphangitis of an extremity or of the trunk, acute inflammation of the scrotum or its contents and lymph node enlargement. The relapsing

nature of the symptoms was verified. Inflammation of the spermatic cord, epididymis, testicle or scrotum, or a combined involvement of more than one of the intrascrotal structures was the most common lesion observed occurring in 192 (71.6 per cent) persons. The usual history was one of a painful swelling of the testicle, which may have been intermittent for weeks or months. The search for microfilariae in the blood remained negative even in those in whom biopsies showed adult female filariae in the lymphatic tissues. The diagnosis of filarial infection can be made by three methods: the finding of adult or larval filariae in tissue obtained at biopsy or postmortem examination; the finding of microfilariae in the blood; or the finding of calcified worms by x-ray. The diagnosis can be established clinically on the basis of a history of a prolonged stay in an endemic area, lymphangitis of an extremity, the trunk or the genitalia coming on after an interval of at least three months, adenopathy, eosinophilia and a positive intradermal reaction. Syphilis, tuberculosis, Hodgkin's disease and all other causes for lymphadenopathy must be ruled out. Filariasis of the spermatic cord has been mistaken for hernia. The intradermal reactions impress the author as being corroborative evidence of past or present infection with Wuchereria bancrofti. The diagnosis should be supported by clinical evidence.

Lesions of Lymphatic System in Early Filariasis—Wartman describes the early lesions of acute filarial lymphadenitis and lymphangitis, due presumably to Wuchereria bancrofti. Material was obtained by biopsy on 17 otherwise healthy young white men who had resided in the islands of the Southwest Pacific for four months and were exposed to the bites of mosquitoes harboring the nonperiodic form of Wuchereria bancrofti. The clinical manifestations included acute epididymitis, acute transient retrograde lymphangitis and lymphadenopathy especially of the upper extremities. Intradermal tests were positive in all but 1 case. Microfilariae were not demonstrated in the peripheral blood. Adult male and female filarial worms were found in 5 of the specimens. Both living and dead worms were present, and the females contained in their uteri large numbers of eggs and microfilariae which appeared morphologically mature. No free microfilariae were found in the tissues. Cultures of the biopsies, as well as tissue sections specially stained for bacteria, were negative, indicating that the lesions were due to the worms and not to bacteria. The tissue reactions in the nodes consisted of granulomatous inflammation with hyperplasia of the macrophage (reticuloendothelial) system and tissue eosinophilia. The lymphatic vessels showed reticuloendothelial hyperplasia, lymph thrombi and varying degrees of inflammation with or without thrombosis. It is suggested that the absence of microfilariae from the blood may be due to the avascular nature of the granulomas, the hyperplasia of macrophages and the small numbers of worms found in the specimens. The history of these patients proves that white persons can be infected during short visits to endemic areas and that signs and symptoms of filariasis may develop as early as three months after the first exposure to infected mosquitoes.

Soy Bean Food in Eczema of Child—Stoesser states that a soy bean food may produce a beneficial effect in eczema of infants and children both in the milk sensitive and in the multiple food sensitive patients. Not all children can take the soy bean formula. Some refuse it and others have gastrointestinal symptoms indicating a possible allergic reaction. Almost one half of the patients develop a diarrhea, but fortunately in most cases this can be controlled.

Pneumonitis Associated with Malaria—Applebaum and Shrager report studies on 125 consecutive patients with pneumonia associated with malaria admitted to Gorgas Hospital during the seventeen month period from January 1942 through May 1943. The most important group, comprising 70 per cent of the total, consisted of young white men belonging to the military personnel. In this group the incidence of pneumonitis associated with malaria as compared with that of uncomplicated malaria was 37 per cent. The disease occurred mainly during the "rainy" season and corresponded in general to the peak of the incidence of malaria and also of pneumonitis. The symptoms, both systemic and respiratory, were similar to the subjective findings of primary pneumonitis. The main objective signs of pneumonitis such as rales, dullness and diminished breath sounds, were likewise elicited. There was a greater percentage of negative findings and additional manifestations of malaria, such as enlarged spleen. X-ray examinations revealed a high percentage of lesions in the lower lobes and of the lobular type. Estivoautumnal malaria and tertian malaria were associated with pneumonitis to approximately the same extent. Negative results of cultures of sputum were reported in the majority of the cases. The white cell counts were normal or showed a leukopenic trend. Complications of pneumonitis were few and not serious. Most of the patients had mild or moderate symptoms. There was only one death, due to cerebral malaria, in the entire series, and the pneumonitis was considered non-contributory. Pneumonitis in malaria is a relatively benign disease and may be classified as (1) atypical or virus pneumonitis, with inadequate response to the therapy employed, running a self-limited course, (2) bacterial pneumonitis, with adequate response to sulfonamide compounds, and (3) malarial pneumonitis, with favorable response to antimalarial drugs.

Fluorescein Method in Peripheral Vascular Diseases—Lange and Boyd show that fluorescein when injected intravenously can be made visible by a beam of long wave ultraviolet radiation on reaching any area of exposed skin or mucous membranes with the blood stream. The physical prerequisites for a good visualization are an appropriate long wave ultraviolet ray source and a dark room. A photoelectric method to indicate the arrival of the dye and to measure the intensity of staining may also be used. Fluorescein is not toxic. Over 1,000 patients have been examined without untoward reactions, except that 11 patients had vomiting of short duration. The dye travels with the blood stream and diffuses immediately through the capillaries into the interstitial spaces. Fluorescein is partly adsorbed to the plasma proteins. Changes in capillary permeability change the amount which diffuses as well as the concentration. Even slight inflammation increases the fluorescence of the tissue. Pigmentation, especially in colored people, makes the test unreliable, although certain basic facts can still be elicited. Nine patients with acute embolism of the legs were examined. It was possible to define exactly the lowest possible level of amputation as far as the skin was concerned and to decide immediately on the probable formation of sufficient collateral circulation to avoid amputation. Block of the sympathetic lumbar ganglions should be performed to avoid mistakes caused by vasospasm. Thrombotic occlusion can be immediately diagnosed. Small gangrenous areas in arteriosclerotic peripheral vascular disease can be judged as to the prospect for healing, localization or further spread. There are two functional types of arteriosclerotic peripheral vascular disease as shown by this test. The first form concerns the larger vessels mainly

causing rapidly spreading gangrene in the periphery, while the other occludes mainly small arteries with capillaries, thereby not necessitating large amputations. Thromboangitis obliterans has usually a higher fluorescence than one would expect from the lack of arterial pulsations. This discrepancy is a leading sign. Spotty fluorescence may complete the picture. Vaso-spastic disorders have a low fluorescence during the attack which immediately returns to normal or even increases above normal on blockage of the sympathetic chain. Rubor on an inflammatory basis in a limb with arteriosclerotic peripheral vascular disease can be well differentiated from venous congestion (rubor on dependence). Thrombophlebitis of superficial vessels can be well made out as long as it is inflammatory, and the extent of the inflammation can be outlined. Ulcers of the leg on a varicose vein basis can be judged as to their outlook for healing and skin grafting. Syphilitic ulcers of the leg have a specific picture in the fluorescein test which distinguishes them from varicose vein ulcers.

*Surgical Treatment of Hypertension Effect of Radical (Lumbodorsal) Splanchnicectomy on Hypertensive State of 156 Patients Followed One to Five Years R H Smithwick —p 180

Surgical Treatment of Hypertension—Smithwick reports the results of lumbodorsal splanchnicectomy performed during the past five years on 156 hypertensive patients, who were followed for one to five years. This is a more extensive procedure than most other operations which have been performed for the relief of hypertension. In all cases the great splanchnic nerves were removed from the semilunar ganglion to the mid-thoracic level or higher. Various portions of the sympathetic trunks were excised. The minimal operation included removal of the tenth thoracic to the first lumbar ganglion inclusive and the maximal operation excision of the sixth thoracic to the third lumbar ganglion inclusive. The effect of operation varies considerably from no change to a distinct lowering of blood pressure. According to the magnitude of the effect on the horizontal resting diastolic blood pressure level the results have been subdivided into five groups. In group 1 there was lowering of 30 mm or more, in group 2 of 20 to 29 mm, in group 3 of 10 to 20 mm and in group 4 up to 10 mm. In group 5 the blood pressure was higher. A study of the postural and cold test charts has revealed certain important differences in the type of hypertension. The patients have been divided into three classes. Patients with narrow pulse pressures, which are less than one-half the diastolic pressure, have type 1 hypertension. Those with wider pulse pressures, equal to or up to 19 mm more than one-half the diastolic pressure, have type 2 hypertension. Those with the widest pulse pressures, 20 mm or more greater than one-half the diastolic pressure, have type 3 hypertension. The result of operation varied with the type, being best for type 1 and poorest for type 3. This subdivision has been helpful in indicating the circumstances under which better results may be expected. Favorable changes in eye-grounds, electrocardiograms and renal function, together with an improvement in the well-being of the patients, suggest that lowering of blood pressure is not harmful. The response of patients with pyelonephritis and hypertension to this form of treatment was unusually satisfactory. There was no significant difference in the results in patients with mild or no renal arteriolar disease as compared with those in patients with more advanced changes. The effect of operation on blood pressure does not appear to be primarily dependent on the state of the renal arterioles, as judged by biopsy material, or on known renal disease, such as pyelonephritis, when present. The results strongly suggest that the state of the extrarenal portion of the visceral vascular bed is important and that the lowering of blood

pressure following operation may be largely the result of decreased peripheral resistance to blood flow through this area. Further observation is needed to determine the duration of the effect.

Proteins in Serum and Cerebrospinal Fluid in Shock

—Duncan and his co-workers compare the nonprotein nitrogen and protein concentrations of serum and cerebrospinal fluid during experimental shock. The type of shock which appeared to be most suitable for this study was that produced by experimental crushing injury, since it has been shown to be characterized by low blood pressure, progressive hemoconcentration, evidence of renal damage and death unless treatment is instituted. Dogs weighing between 7 and 12 Kg were used as experimental animals. The mean concentration of protein in the cerebrospinal fluid of the animals in shock was greater than the corresponding value for the control group. However, this increase was of small magnitude and may be explained on the basis of a slight shift of water from the spinal fluid resulting from the hemoconcentration. The mean ratios of the concentrations of protein in serum to the corresponding concentrations in cerebrospinal fluid were essentially the same for the two groups of animals. These experiments indicate that if alteration in the barrier relationship between plasma and cerebrospinal fluid does occur in shock produced by this method it is not sufficient to permit extensive passage of plasma proteins into the spinal fluid.

Polyvinyl Alcohols as Blood Substitutes—Roome and

his associates compared the supportive effect on the blood pressure of several grades of polyvinyl alcohols with other materials after severe hemorrhage. Their experiments were made on dogs, in which half of the blood removed was replaced by various agents including citrated dog blood, citrated plasma, acacia and three grades of polyvinyl alcohols. The studies revealed that polyvinyl alcohol Rh623 is a suitable colloid for a plasma substitute. It maintained the blood pressure as well as did blood transfusions. It was lost from the blood stream in dogs at about the same rate at which the plasma proteins regenerate. Solu-

tions of 4 per cent polyvinyl alcohol Rh623 were given to 4 human subjects. There were no untoward effects. Dilution of the blood occurred and persisted for twenty-four hours after large doses. Inert substitutes, however, do not promote wound healing or act as foodstuffs, as a protein might. They do not contribute to hemostasis. Large amounts might impede clotting by diluting the fibrinogen. Their nonprotein nature is also an advantage in lessening the likelihood of anaphylactic reactions. They obviously do not provide antibodies and erythrocytes and hence are valueless in anemias and in infections except to improve the peripheral circulation. If limited to its proper field polyvinyl alcohol would appear very desirable as a first treatment for hemorrhage or shock, assuming that hemostasis can be obtained or that direct bleeding is not a prominent feature. Its small cost, ease of preparation and stability in storage would permit keeping it available for emergency use in amounts larger than can be economically kept in a blood or plasma bank.

Pentothal Sodium in an Army Anesthesia Service—

Boddington shows that pentothal sodium has gained a deserved popularity in army anesthesia practice. In a Canadian camp hospital sodium pentothal was used in 35 per cent of the cases requiring anesthetics. It is equally popular with patient, surgeon and anesthetist. Referring to the mild state of euphoria sometimes occurring with the return to consciousness, soldiers have dubbed pentothal "the G I drunk." A preoperative sedative consisting of morphine $\frac{1}{4}$ grain (16 mg) and atropine $\frac{1}{150}$ grain (0.4 mg) is given three quarters to half an hour prior to operation. The 5 per cent solution of pentothal has been used in almost all cases. The apparatus consists of a syringe and needle. Any suitable vein may be used but most often it is the antecubital vein. At the beginning of the anesthesia an injection of 3 cc is made. The anesthetist then chats quietly with the patient or instructs him to count. Thirty-five seconds later an additional 2 cc is added. Additional amounts of 2 cc are given as required. The level of anesthesia is gaged by the depth of respiration, eye movement, conjunctival reflex, muscular relaxation and response to stimulation. Because of the respiratory depression, oxygen is always kept close at hand. As contraindications to anesthesia with sodium pentothal the author mentions impaired pulmonary ventilation, respiratory obstruction and liver disease.

Massive Dose Therapy of Early Syphilis—Berry and

Mitchell have used the five day massive dose therapy of syphilis for four years. They had treated over a hundred cases up to the end of 1942. The authors were able to follow 50 of these cases. While troublesome complications, such as pain in the arm, fever or nausea, occur in a sufficient proportion of cases to make the treatment somewhat unpleasant, serious complications are relatively infrequent. They do occur sufficiently often so that vigilance can never be relaxed. The most dreaded complication is hemorrhagic encephalitis. The authors observed this complication in 1 case, which had a fatal outcome. A second complication was one of toxic hepatitis and polyneuritis. This patient was last seen nearly a year after treatment and at this time he still had a good deal of numbness of his hands and feet and could walk only with the use of a cane. His blood and spinal fluid were normal. Two other serious complications are acute nephritis and exfoliative dermatitis. These conditions are much less common and do not constitute a hazard peculiar to the intensive type of treatment. Eleven patients who have been followed for three years are known to have negative blood. The same is true of 12 patients who have been followed for two years and of 23 patients who have been followed for over one year. One patient, who was treated in November 1940, was found to be positive in March 1941. A boy of 13 with primary syphilis was given 1,320 mg of mapharsen in the course of six days. This excessive amount was well tolerated. Three months later the boy's blood was negative, but after six months it was positive again. The authors describe an unusual case in which the five day method of antisyphilitic treatment seems to have saved the patient's life.

Acute Acetone Poisoning—Strong's patient was a man aged 42 who had had a giant cell tumor of the ligamentum teres removed and on whom an arthrodesis had been done. Because there was still incomplete union after the second cast

had been removed a body spica was applied to protect the hip and allow walking with the knee free. For this third cast a material lighter than plaster of paris a compound consisting of polymerized vinylacetate, pyroxylin, boric acid, acetone and surgical gauze was chosen. This was applied over two layers of stockinet. Following the application of the material a lacquer also an acetone-containing product was applied and two and a half hours was spent with hot air blower and suction apparatus in an attempt to dry the cast. The patient was returned to his room at 4 p. m. in good condition. At 7 o'clock he refused his supper and at 11 p. m. developed nausea and vomiting. At 2 a. m. the patient vomited large quantities of brown material. He became gradually more and more difficult to arouse, so that by 6 a. m. he was semiconscious. The patient presented the picture of a severe diabetic coma. It was suggested by consultants that the man had had diabetes and that application of the cast had precipitated a coma. A severe ketosis was produced like that occurring in diabetic coma. There was no acidosis, however, as shown by the normal carbon dioxide combining power of the blood. Hemorrhagic esophagitis was a prominent feature. The hemorrhage was aggravated by the presence of the Levine tube. The fact that urticaria-like welts were found on the skin after the removal of the cast raises the question of idiosyncrasy. It is to be noted, however, that the patient himself had used this material in the application of casts to his own patients without irritation of the skin of his hands. The question whether the acetone was absorbed through the intact skin or by inhalation is an open one. It would appear that the latter route was more likely. Nothing in this report should be taken as a condemnation of the material used. The lacquer in this instance was applied before the cast had had a chance to dry.

Transurethral Drainage in Seminal Vesiculitis—Herbst and Merricks discuss involvement of the seminal vesicles in association with obstructive vesiculitis, prostatic calculi, hematospermia and obstructive sterility. When routine adequate treatment by massage and instillations, with removal of distant foci of infection, fail to relieve infection involving the prostate and seminal vesicles, satisfactory results may often be obtained by providing adequate drainage of obstructed infected seminal vesicles. Transurethral dilation of the ejaculatory ducts alone or at times combined with transurethral prostatotomy for removal of prostatic calculi are the methods of choice. By these procedures the fundamental surgical principles of drainage of these organs is best obtained. The authors have performed transurethral dilation and catheterization of approximately 730 ejaculatory ducts.

Arteriovenous Fistula of Lung Cured by Pneumonectomy—According to Jones and Thompson arteriovenous fistula of the lung usually masquerades in a cyanotic young patient with clubbing of fingers and toes as congenital heart disease or polycythemia until either a tumor of the lung or a continuous murmur in the chest is finally discovered. The authors report the history of a woman aged 24 who had been cyanotic from birth and intensely so until the age of 16. Clubbing of the fingers began at the age of 9 years increased until 16 and then remained stationary. Her activities were restricted until the age of 16 but subsequently she became quite active without symptoms. Eighteen months before being seen by the authors the patient was examined by an internist, and for the first time x-ray examination revealed an intrathoracic mass. On a presumptive diagnosis of tumor a course of radiation therapy was given, but it affected neither the mass nor the cyanosis. At that time polycythemia was noted and thought to be primary. The red blood cell count had ranged between 65 and 75 millions with a hemoglobin of 130 per cent for the last one and one-half years. She had been working steadily as a stenographer and leading a normal life. The conjunctivas and mucous membranes were intensely cyanotic. A provisional diagnosis of arteriovenous aneurysm of the right lung was made on the history of cyanosis since birth the persistent secondary or symptomatic polycythemia, the presence of a continuous murmur over the tumor mass in the right lung, clubbing of the fingers and a normal heart. Pneumothorax on the right side was tried in the hope that it might collapse the arteriovenous communication. The pneumothorax was maintained for five months, but, since it had been impossible to collapse the fistula, surgical treatment was considered necessary. A right total pneumonectomy proved necessary and was done by dissection and individual ligation. A checkup four months after the operation revealed that the patient was well and leading an active life. To the question why surgery should be performed on a young patient

when the lesion has imposed no incapacitation, the author states that rupture of the fistula led to sudden death of Rodes's patient and that in his own patient the sac was extremely thin. There is also a hazard of thromboses secondary to the polycythemia.

Ocular Manifestations of Malaria—According to Robertson, optic neuritis and amblyopia are at times associated with malaria. The amblyopia has to be differentiated from that which is due to quinine. In quinine amblyopia the condition depends on the retinal anemia resulting from the toxic spasm of the arterioles, there is extreme pallor of the optic disks and contraction of the visual fields. This picture is in direct contrast to the hyperemic disk and retina associated with malarial toxemia. Malarial amblyopia occurs as a result of the action of the malarial toxin on the optic nerve and retina. Often optic neuritis and papillary edema result from the blocking of the retinal and choroidal vessels by parasites and leukocytes. The retinal hemorrhages are usually small, multiple and peripheral, large macular hemorrhages do occur in the malignant types of malaria. Ulceration of the cornea is the most common ocular sequela of malaria, and recurrent iritis is frequently associated with this keratitis. Supraorbital neuralgia precedes the corneal lesions. Photophobia and lacrimation are characteristic signs and often precede the corneal lesions by days or weeks. On an island in the Southwest Pacific the author encountered many patients with intraocular disturbance among men between the ages of 20 and 30. Many had suffered some depletion of the powers of accommodation and convergence, as was manifested by the complaints of reading difficulties, scotomas and muscle imbalance, particularly exophorias. Subjectively the complaints were loss of vision, frequent headaches in the occipital and temporal regions, dizziness, pain in the eyeballs, tenderness on palpation, photophobia, lacrimation and spots before the eyes. The objective findings were irregularity of the pupils, retinitis of the atrophic type, usually in or around the macular area, unusual concentration of choroidal pigmentation, generalized hyperemia of the retina and nerve head, optic neuritis both mild and severe, optic atrophy and in a few cases a severe progressive choroidoretinitis and uveitis. Some of the patients who were evacuated were followed up by the author since his return. Some of them now have a chronic uveitis.

Roentgen Therapy in Gas Bacillus Infection—Cantril and Buschke present 9 cases to demonstrate that x-ray therapy can in itself, or in conjunction with surgery, save patients with an overwhelming gas bacillus infection superimposed on the shock of severe trauma. The interval between injury and x-ray therapy varied between six hours and nineteen days. Five patients received antitoxin therapy and 4 did not. One patient received only 10,000 units and developed a severe serum reaction. The other 4 patients received it in full therapeutic amounts. Chemotherapy in the form of sulfonamide was administered to all but 3 of the 9 patients. There was no evidence that chemotherapy had a place in controlling the progression of the gas bacillus infection. When used to combat the secondary bacterial invasion after the spread of gas infection had been brought under control it seems to have produced good results in 3 cases. The mortality in the 9 cases was zero, but the authors do not expect that this record can be maintained. A mortality of 112 per cent in 125 cases, as reported by Kelly, still represents a large saving in lives over reports prior to the use of x-rays in this disease. X-ray therapy has saved both lives and limbs in gas bacillus infection. The combination of surgery and x-ray therapy can produce results not heretofore obtained by any approach to this most severe complication of traumatic wounds.

Effects of Endocrine Therapy on Bone Growth—According to Finkler and her associates the effect of endocrine therapy on growth in children has been under investigation in the Endocrine Clinic of the Beth Israel Hospital for the past eight years. The influence of endocrine therapy on bone growth has been observed in 81 children, 18 of whom were treated with thyroid substance, 26 with anterior pituitary growth extract, 19 with chorionic gonadotropin and 18 with testosterone. Thyroid therapy tended to improve bone density and epiphyseal union. At the conclusion of therapy the bone density was normal in all children, but in 5 the delay in epiphyseal union persisted. There was an improvement in growth rate, physical development and mental alertness. Best results were obtained in children with thyroid deficiency. Therapy with anterior pituitary growth extract did not yield conclusive evidence of changes in skeletal growth in the majority of the 26 patients. There was, however, a general improvement in vitality, muscle tone and mental alertness in the majority of the children. Chorionic gonadotropin therapy stimulated bone growth in the longitudinal axis but did not accelerate epiphyseal union, bone maturation or density in the majority of the cases. Seventeen children responded by an increase in growth rate, 2 children maintained their original rate of growth. All children showed an improvement in genital development, muscular tone, mental alertness and social adjustment. There was also a loss of weight in the majority of the obese children. Testosterone therapy showed a tendency to accelerate skeletal growth in length to a somewhat greater degree than chorionic gonadotropin. Clinically 16 children showed an increase in growth rate and 2 maintained their original rate of growth. All children showed improvement in genital development, muscular tone and self assurance. Before endocrine therapy all the children presented various psychologic maladjustments. Following endocrine therapy, with improvement in growth and genital and muscular development there was a tendency to improvement in mental and emotional stability.

Artificial Respiration in Asphyxia—Tingley points out that the rate in all methods of artificial respiration varies between twelve and eighteen times a minute. It is his aim to demonstrate the error in the application of all methods of artificial respiration to cases of asphyxia without at the same time considering the greatly increased respiratory requirements. All cases for which artificial respiration is required fall into two main groups: group 1, cases without asphyxia, e.g., under anesthesia, from electric shock; group 2, cases with asphyxia, e.g., suffocation from drowning, from lack of air from smoke, from gases. Artificial respiration done at the usual rate of fifteen times a minute is adequate and excellent for group 1 cases, as the respiratory requirements are approximately the same as in natural respiration at rest, but the same rate is quite inadequate to deal satisfactorily with group 2 cases of asphyxia. He differentiates three degrees of asphyxia: degree 1 up to loss of consciousness; degree 2 up to cessation of respiration; degree 3 up to final heart failure. He describes experiments on degree 1 asphyxia which revealed that the deeper the asphyxia the greater is the respiratory requirement, that the total volume of air exchanged in a given time largely determines the extent of relief from asphyxia and that the faster the rate of tidal respiration the greater the relief from asphyxia. In every method of artificial respiration employed at present the rate is slow. Four seconds is a long time when applied to one respiratory cycle. In most methods it has been necessary to include a pause of one to two seconds in each cycle in order to keep the rate down to the so-called normal. He thinks that in natural respiration for even mild degrees of asphyxia there is no time for a pause at all. In Schafer's method it is difficult to occupy fully three seconds with the actual movements necessary for one cycle. It is much cruder, and just as effective, to do all the movements in two seconds instead of three. The second so saved could be utilized along with the second previously set aside for an inter-

val, by providing the two seconds necessary for another cycle. Thus the rate may be doubled without undue effort. This rate of thirty times a minute can be doubled again. It is not difficult to do Schafer's method at a rate of sixty times a minute without loss of volume per respiration. Silvester's method, because of the nature of the movements necessary, takes more time to perform than Schafer's, and a rate of about forty-five times a minute would seem to be the efficient maximum.

Influence of Synthetic Estrogens on Advanced Malignant Disease—Haddow and his associates report observations on 40 cases of carcinoma of the breast and 33 cases of malignant disease of other organs. These 73 patients with advanced cancer were treated with the synthetic estrogens triphenylchloroethylene, triphenylmethylethylene or diethylstilbestrol. Of 22 cases of late malignant disease of the breast treated with triphenylchloroethylene (usually in doses of 3 to 6 Gm per day) 10 showed a significant although temporary retardation or even partial regression of the tumor. No evidence was obtained to suggest that the drug will prevent the development of metastases. The initial effect of treatment in these cases passed off comparatively rapidly, and only 1 has shown prolonged arrest, the ultimate course of the disease being in no way altered in the remainder. The degree of retardation was less than could be expected from local palliative x-irradiation. Of 30 cases of advanced malignant disease other than cancer of the breast (including carcinoma of the skin, maxillary antrum, urinary bladder, ovary, rectum and testis with reticuloendothelial growths and leukemia) and similarly treated with triphenylchloroethylene, only 2 showed undoubted partial regression of the tumor. Of 4 cases of mammary cancer and 3 cases of Hodgkin's disease treated with triphenylmethylethylene only 1 showed even a temporarily favorable response. Of 14 cases of carcinoma of the breast treated with diethylstilbestrol, 5 showed alterations in the growth and behavior of the tumor similar in nature to those produced by triphenylchloroethylene. Serial biopsies in cases with clinical response showed microscopic alterations of a type not resembling the changes following x-irradiation. The secondary signs of drug action included nausea, pigmentation of the mammary areola, mastitis in the male, uterine bleeding and edema of the lower extremities. One or more of such changes occurred with special frequency in cases showing some degree of tumor regression. Several of these patients also manifested improved appetite, gain in weight and diminution of pain.

Fatal Purpura After Sulfapyridine—Sherlock and White observed acute purpura during the course of sulfapyridine therapy of pneumonia in a man aged 52. He was given 30 Gm of sulfapyridine in seven days, and the immediate response was satisfactory. However five days after cessation of treatment there was a rise of temperature. Recrudescence of pneumonia or empyema was considered. Sulfapyridine therapy was restarted 4.5 Gm being given during the next five days. The malaise and pyrexia persisted. It was noted that the temperature rose after each dose of sulfapyridine. Then a slight epistaxis developed, and several days later an extensive purpuric eruption appeared on the palate, arms and legs. Epistaxis persisted, and blood was oozing from the gums. He vomited coffee ground material giving a positive benzidine reaction. The urine, normal in quantity, had become frankly blood stained. The ankles presented pitting edema. Later purpura was even more gross, and blood was flowing freely from the nose and mouth. Compatible blood was transfused. As the procedure was started the patient complained of a bursting sensation in the head two and one-half hours later he was in coma. Several hours later the patient died. The authors are convinced that the patient's fatal illness was the result of sulfapyridine. Necropsy disclosed that pneumonia had resolved. The authors think that vascular lesions caused the fatal purpura. The effect

on the vessels may be due to hypersensitivity. If drugs are administered in two courses, hypersensitive phenomena are more likely to occur. In the reported case the drug was given for seven days, then a five day interval was allowed to elapse before restarting it. It was only on the second occasion that the supposed intolerance became apparent. The high mortality of this condition makes early recognition essential. The first clinical sign is nearly always epistaxis. If this or other spontaneous bleeding is discovered in a patient receiving sulfonamide drugs, the administration should be stopped immediately and a bleeding time and capillary resistance test done. Adequate transfusion of fresh blood is probably the best treatment.

Congenital Dental Defects and Maternal Rubella During Pregnancy—Evans points out that the association of congenital defects in infants with maternal rubella during pregnancy is now well established. The parents of each infant were questioned with regard to the time of eruption of the teeth, especially the first, and the occurrence of convulsions. Each child was examined from the point of view of such dental defects as (a) variation in the number of teeth from normal, (b) hypoplasia, (c) abnormal tooth form, (d) restricted arch formation, (e) dental caries and (f) gingivitis. Of 34 babies whose mothers suffered during pregnancy from German measles, 23 exhibited congenital dental abnormalities, in 18 cases major in nature. All except 2 of the infants with dental defects showed other congenital malformations. There were also other defects such as deaf mutism, cataract, heart disease, microcephaly and mental deficiency. With the exception of 2 cases the mothers of all the children with congenital dental abnormalities had contracted rubella at some period during the first three months of pregnancy. Dental defects were most severe in infants belonging to the mothers who had suffered from German measles between the sixth and the ninth week of pregnancy, considered to be the "critical" period of dental development. The main dental abnormalities comprised retardation of eruption, enamel hypoplasia and dental caries.

- *American Visceral Leishmaniasis Case O Monteiro de Barros and G Rosenfeld—p 97

American Visceral Leishmaniasis—Monteiro de Barros and Rosenfeld direct attention to the importance of splenic puncture for the diagnosis of American visceral leishmaniasis. The authors' patient, 19 years of age, complained for eight months of symptoms suggestive of malaria. The progressive anemia and emaciation did not respond to malarial therapy. There was enlargement of the spleen but no malarial parasites on repeated

blood examinations. American leishmaniasis were identified in preparations from material obtained by puncture of the spleen. Treatment consisted of intramuscular injections of Neostibosan (a pentavalent antimony compound) in doses of 6 cc (0.30 Gm) each, every other day up to a total number of thirty injections. Antianemic therapy was also administered. Permanent recovery and disappearance of splenomegaly followed.

Neoplastic Cells in Sputum—Wandall states that the cytologic examination of sputum may become an aid to the roentgenologic and bronchoscopic examinations in diagnosis of primary pulmonary carcinoma. The roentgen station and the surgical department of the State Hospital in Copenhagen examined the sputum in 60 cases. Diagnosis of primary pulmonary carcinoma was made in 30 cases; diagnosis of secondary pulmonary carcinoma in 5 and diagnosis of a benign bronchial tumor in 1 case. Twenty two of the 30 cases of primary pulmonary carcinoma were confirmed histologically, while the remaining 8 were roentgenologically positive. In 19 of the 22 histologically confirmed cases and in 7 of the 8 roentgenologically positive cases neoplastic cells were demonstrated in the sputum. In the case of the benign bronchial tumor neoplastic cells could not be demonstrated in the sputum. Neoplastic cells were found in the sputum of patients with metastases to the lung from osteosarcoma, hypernephroma, carcinoma of the ovary and seminoma. The frequency of neoplastic cells in the sputum depends on the extent, the localization and the histologic type of the tumor. Thirteen of the 22 histologically verified cases were inoperable. In 12 of these 13 cases neoplastic cells were demonstrated in the sputum. In the remaining 9 cases it was decided to operate. Seven of the cases proved inoperable. Radical operation was performed in 2 cases, both of which presented neoplastic cells in the sputum. Two cases presented a peripheral localization of the tumor. Neoplastic cells were demonstrated more frequently in the differentiated than in the undifferentiated types of tumor.

Chemotherapeutic Effect of p-(Aminomethyl)-Benzenesulfonamide ('Marfanil')—Schmith reports studies in which, among other compounds, p (aminomethyl)-benzenesulfonamide ("Mesudin," "Marfanil") has been examined as a link in a systematic investigation on the relationship between the chemical structure of the sulfonamides and their bacteriostatic effect. These studies showed that p-(aminomethyl) benzenesulfonamide has a chemotherapeutic effect of a fundamentally different character from that of the other sulfonamides. The effect of this substance is not neutralized by para-aminobenzoic acid. It has just as strong a bacteriostatic effect on the resistant strains as on the sensitive strains of bacteria. P-(aminomethyl)-benzenesulfonamide is able to reduce the number of bacteria at once, i.e. without any initial phase of growth. The effect of p-(aminomethyl)-benzenesulfonamide does not depend on the size of the inoculum; i.e. its effect on large inocula is not weaker than that on small inocula. So far, p-(aminomethyl)-benzenesulfonamide has been employed clinically only to such a slight extent that it would be impossible to say anything about its therapeutic value. Further experiments are necessary to ascertain whether its effect may be increased by the introduction of heterocyclic substituents as in sulfanilamide.

Book Notices

The Blood Pressure and Its Disorders Including Angina Pectoris By John Plesch M.D. Cloth Price \$3.50 Pp 149 with 61 illustrations Baltimore William Wood & Company 1944

This little monograph with its overly ambitious title and high price, is concerned primarily with a thorough discussion of the theory, technique and interpretation of tonoscillographic mensuration of the vascular tension. As a research monograph on this particular phase of abnormal physiology of the circulation it is a stimulating book of interest to those internists and investigators concentrating their attention on hypertensive arterial disease. To others it offers little that is useful. The approach to the multifaceted and complex problems of circulatory disease lacks breadth of view and clinical insight. Etiology, pathogenesis and prognosis are mentioned only superficially. The discussion of therapy in hypertension in general and for angina pectoris in particular is a curious mixture of archaic and modern concepts. It was rather a shock to discover the author advocating blood letting in angina pectoris. As an alternative he suggests a reduction of blood volume by a diet low in protein sodium chloride and other water-retaining substances. Such concepts hardly warrant attention today.

Dr Plesch according to the title page was formerly professor of internal medicine in the University of Berlin. His presentation therefore gives us some insight into recent continental medical thinking. Apparently it has not changed appreciably remaining purely somatic in point of view. The psychosomatic aspects of cardiovascular disorders are totally ignored. His presentation is wholly individualistic no consideration is given the significant literature on hypertensive disease which has been accumulating over the last twenty years. Though the author's discussions are clear and the text well written, the dogmatic assurance of finality is unlike that of a true scientist, who invariably doubts his own conclusions. The book can be recommended only to those who are particularly interested in circulatory disorders and sufficiently advanced students of these problems to read it critically. It can perform no particular service for the general practitioner or internist of broad interests.

La organización de la Universidad y la Investigación científica Por el Prof. Dr. Alejandro Lipschutz director del departamento de medicina experimental del Servicio nacional de salubridad. Paper Price 25 pesos Pp 216 Santiago Chile Editorial Nascimento 1943

The author has published a series of lectures delivered in different cultural institutions of Chile in which he approached varied problems concerned with education, science, culture, philosophy, religion and politics. The reader has the impression that the author has taken advantage of these opportunities to expose those points of view that every cultured person has about the complexities of life and which, in general are kept as a subject for private conversations of a high intellectual sort. This sort of lecturing can be highly instructive and amusing especially if the lecturer presents his subject with both clarity and charm, as undoubtedly Dr Lipschutz did. The frequent imperfections of the Spanish used which are obvious to the eyes of the Spanish authority, no doubt passed unnoticed to the ears of the listener.

Ourselves Unborn An Embryologist's Essay on Man By George N. Corner The Terry Lectures 1944 Cloth Price \$3 Pp 183 with 18 illustrations New Haven Yale University Press London Oxford University Press 1944

The Terry Lectures were established at Yale so that the truths of science and philosophy might be integrated into 'a broadened and purified religion'. The committee for the last lectures selected embryology as the science and Dr George Corner as the interpreter and integrator. The excellence of this little book is conclusive evidence of wisdom in both selections. Embryology is significant for religion and Dr Corner is a capable scholarly and sympathetic interpreter.

The book is brief, being concluded in three chapters. In the first Dr Corner with consummate skill describes briefly in intelligible and nontechnical terms what to anatomists is the most wonderful phenomenon in our universe—the phenomenon in which one microscopic particle of protoplasm becomes by self impelled progression a living man—perhaps another Shake-

speare or a Newton. This is the miracle of Ourselves Unborn. We are at that stage both germs and archives—germs because that small but busy bit of life becomes a man with all his hopes, ideals and religion—archives, because its life is just the life of our ancestors continued in a line necessarily unbroken from the beginning of life on this planet and reporting and repeating in its progress the long history of its past.

The second chapter deals with accidents during life in the womb before birth. These accidents are so common that from one third to one half of us die then mostly unrecognized even by the mothers. Religion prompts the questions: Did these dead have souls? Have they eternal life? Is one of them because unbaptized a little soul playing in a green field outside the gates of heaven not in torment nor even unhappy but certainly very wistful because he is not permitted to walk hand in hand with his mother before the Throne of Grace?

The third chapter deals with embryologic evidence of our place in nature and our evolutionary origin. It concludes that we are in intimate relationship with the animal world tempered by powers of the mind that bestow dignity and honor upon the life of the body.

An index helps in the study of this fascinating book and a bibliography will show some interested readers how to make a more thorough and intensive study. Dr Corner has provided a reliable and inspiring vision of our earliest days and his book is a contribution to literature as well as to science and religion.

Technic of Electrotherapy and Its Physical and Physiological Basis By Stafford L. Osborne M.S. Ph.D. Assistant Professor Department of Physical Therapy Northwestern University Medical School and Harold J. Holmquest B.S. B.S.(M.E.) Cloth Price \$7.50 Pp 789 with 241 illustrations Springfield Illinois & Baltimore Charles C Thomas 1944

This excellent new textbook dealing with a limited but important phase of physical medicine is divided into four parts. The first part deals with the effect and technical application of the direct current, the second with electrical stimulation of muscles, the third with radiation and the fourth with high frequency electrical currents.

The authors are eminently qualified to present the subject with which they are dealing. Osborne as a trained physiologist who has devoted many years to the subject of physical medicine, and Holmquest, the qualified physicist who has interested himself particularly in medical physics have collaborated in presenting a difficult subject in an understandable fashion.

The authors state that the book has been written with two groups of students in mind: first those who are well grounded in science and who desire a thorough and comprehensive training in the fundamentals of electrotherapy for whom the more advanced work in physics and mathematics appears in the form of footnotes; second, those students whose training in science is limited and who might therefore find the subject matter in the footnotes difficult to follow. For the latter group of students the technical material in footnotes may be eliminated without interfering with the clarity or continuity of the text. The authors have succeeded very well in their purpose and the procedure which has been described has been accomplished successfully.

This textbook is unquestionably the most complete modern volume on the physical and physiologic basis of electrotherapy. Every physician who is interested in physical medicine and every physical therapy technician would do well to study it carefully. The authors are to be congratulated on a difficult task well done.

Del estado del niño del médico Por Eduardo D. Ocampo Garl. Tesis del alumno Universidad nacional de Buenos Aires Facultad de ciencias medicas Escuela de medicina Paper 1p 131 with illustrations Buenos Aires Guillermo Kraft Ltda. Sociedad Anonima de Impresiones Generales 1942

The first chapter includes useful statistics on childbirth and infantile mortality in the city of Buenos Aires. The second chapter deals with the measures taken in different countries for the protection of mothers and the infantile population. The third chapter deals with analogous measures in the Argentine Republic and gives interesting statistical and graphic information on a model kindergarten in Buenos Aires, the "Jardín de la Infancia Mitre." The last chapter summarizes the topic and draws plans for the future.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EFFECT OF CAFFEINE ON HUMAN BEINGS

To the Editor—What is the present opinion on the effect of caffeine on human beings and the possibility of hypercaffeinemia? Are there recent studies on the subject?

Bennett W. Kantola, Lieutenant (MC) U.S.N.

ANSWER—As ordinarily taken in beverages, caffeine produces a mild stimulation of the cortical centers characterized by wakefulness and alertness. In some persons or with larger amounts restlessness, muscle tenseness, and an inability to concentrate are also produced. There is little effect on the medullary centers and peripheral organs except for mild diuresis until medicinal doses are administered. Then there may be respiratory and circulatory stimulation. With extratherapeutic doses these effects become more pronounced and delirium may be produced but fatal poisoning is almost unknown. A certain amount of tolerance is produced by continued use of beverages containing caffeine, and headache has been described as a withdrawal symptom.

Moderate continued use of beverages containing caffeine would not appear to be harmful. Immoderate use probably impairs both mental and physical performance in the direction of inexactness and misjudgment.

TEST OF LABOR OR CESAREAN SECTION

To the Editor—A slender white woman aged 35 is six months pregnant. She had one other child seventeen years ago. She has had several cervical cauterizations; the right kidney has been removed; her tonsils have been removed; a Baldy-Webster suspension has been done. She has been in a psychopathic hospital and her case diagnosed as hysteria. Another psychiatrist diagnosed her condition as true convulsive seizures. Should this woman be delivered by cesarean section or given a test of labor?

M. D. Texas

ANSWER—A patient like this should preferably be given a test of labor and delivered from below. Hysteria or convulsions are not indications for cesarean section; neither is the nephrectomy, the cervical cauterization or the Baldy-Webster suspension. Normal labor is less of a strain than an abdominal operation in a secundipara with one kidney; the majority of women have normal labor following nephrectomy. Likewise if the cauterization was properly performed there should be no interference with the first stage of labor. This woman should have much more supervision than other women during the remainder of her pregnancy. She should have at least weekly examinations of the urine and Mosenthal tests of renal function to be certain that trouble does not arise in the one kidney she has. Should evidence of nephritis, toxemia or severe pyelitis appear, the pregnancy should be terminated. However, there need not be alarm in finding albumin in the urine during the last few weeks, because this occurs in more than half the cases of pregnancy following nephrectomy. If any obstetric indication for cesarean section arises, fear of performing the operation is not indicated, but it should not be an elective one simply because of the patient's past history.

TRANSFUSIONS WITH POLYCYTHEMIC BLOOD

To the Editor—Is there any contraindication to the use of polycythemic blood in transfusion work? In the case of a person with polycythemia whose hemoglobin is 20 Gm and red blood cell count is 8,000,000, what should be the dilution with isotonic solution of sodium chloride in the event that this blood can be used?

M. D. Brooklyn

ANSWER—Since the cause of polycythemia vera is still unknown, the possibility cannot be excluded that the disease may be transmissible by blood transfusions. In addition as the best policy is to use only perfectly healthy donors, the use of polycythemic blood for transfusion may be objectionable. There should be no mechanical difficulty in transfusing polycythemic blood, so there is no need to add any saline solution. When packed red cells are used for transfusions, the usual policy is to restore the original volume by adding a volume of saline solution equal to the volume of plasma removed. However, some workers transfuse the packed cells without adding saline solution or adding only minimal amounts sufficient to reduce the viscosity.

DERMATITIS FROM SMOKE AND FUMES

To the Editor—A woman aged 35 suffers from a dermatitis caused by contact with smoke fumes or any product of combustion of kerosene, coal, wood, even the fumes from the exhaust pipe of an automobile. A rash appears on all exposed surfaces and resembles a weeping chronic eczema. She first consulted me about this condition in March 1943 and since then has consulted many other physicians, including several excellent dermatologists who have been unable to provide or suggest any means of relief. Please forward any information that may be of help in desensitizing or treating this patient.

D. K. Matthews, M.D., Dresden, Ohio

ANSWER—Dermatitis from exposure to fumes is rare. Search of the literature failed to reveal any definite cases of this nature. Tuft (Clinical Allergy, Philadelphia, W. B. Saunders Company, 1938, p. 508) mentions contact dermatitis from occupational dusts of all kinds and from certain hydrocarbons, e. g. raw petroleum lubricating oils, cutting emulsions, benzene, naphtha and carbon disulfide. Such cases are frequent. Shelmire mentions that a patient susceptible to contact with poison ivy did not develop dermatitis when exposed to the smoke of burning poison ivy plants (*Arch. Dermat. & Syph.* 43: 384 [Feb.] 1941). Avoidance of fumes seems to be the only important method of treatment. Desensitization or hyposensitization is impossible because proper extracts cannot be readily made, and even if they could be correctly prepared, the results of treatment would probably be unsuccessful.

INDUCTOTHERMY AFTER IMPLANTATION OF METAL PIN

To the Editor—Will the use of inductothermy in a case in which a metal pin has been placed for fracture of the neck of the femur be permissible? Is there experience to indicate whether calcification of callus may be induced?

J. D. Holston, M.D., Massillon, Ohio

ANSWER—It would be better not to use inductothermy in a case in which a metal pin has been placed for fracture of the neck of the femur. With ordinary treatment dosages it is probable that the danger of excessive heating of the pin is slight; nevertheless it could occur. There is no definite proof that hyperemia in itself would promote more rapid repair of the fracture, although some experiments have pointed that way. On the other hand, it is generally agreed that excessive hyperemia could cause decalcification.

One of our large military medical centers now, it is believed, is carrying on extensive studies on the effect of diathermy on metallic implants, but thus far no conclusions have been reached. Therefore it would seem better, for the present, to avoid the use of a short wave diathermy induction coil over a metallic implant.

RABBITS VERSUS FROGS FOR ECTOPIC PREGNANCY TESTS

To the Editor—I should appreciate an opinion relative to the incidence of positive Aschheim-Zondek tests in ectopic pregnancy. It is my understanding that the rabbit is most frequently negative but the frog test is positive in a high percentage of cases. Is this correct?

A. A. Skemp, M.D., La Crosse, Wis.

ANSWER—In order to obtain a positive test for pregnancy using either the rabbit or the frog for the test, it is necessary to have an excess of chorionic gonadotropin in the blood or the urine of the patient to be tested. Since in many ectopic pregnancies there is a poor development of the trophoblast or the chorionic villi plus a poor connection with the maternal tissue, the incidence of negative tests for pregnancy is high. In most series the discrepancies run to about 25 to 30 per cent, so that the Xenopus (frog) test will not show a higher rate of positive tests in ectopic pregnancy than will tests on the rabbit. The only advantage of the frog test over the rabbit test is that it is possible to obtain a result in the former in eight hours while the latter needs eighteen to thirty-six hours of running time.

DEAFNESS FROM MENINGITIS

To the Editor—Is there any new treatment now available for a patient who is totally deaf as a result of meningitis fifteen years ago, which apparently destroyed the auditory nerves? His inner ear mechanism is apparently intact for he has no trouble with his balance or with vertigo.

C. Ronald Fulkerson, M.D., Oskdale, Calif.

ANSWER—Deafness from meningitis is always due to invasion of the inner ear by the infection with destruction of the nerve of hearing. Generally the static labyrinth is destroyed along with the acoustic labyrinth as could be determined by the caloric test. The fact that the patient is no longer unsteady or dizzy is not surprising, since compensation occurs after both labyrinths have been completely destroyed. There is no possibility of any improvement in the hearing by medical or surgical means in such a case. Lip reading must be resorted to.

THE PRESENT STATUS OF THE SURGICAL TREATMENT OF PRIMARY CARCINOMA OF THE LUNG

WILLIAM FRANCIS RIENHOFF JR, M D
BALTIMORE

Slightly more than one decade has elapsed since the first one stage total pneumonectomy in the Johns Hopkins Hospital was performed on July 24 1933¹ After extrapulmonary individual ligation of the hilar structures the entire left lung was removed from a 3½ year old girl for primary fibrosarcoma of the left main bronchus The child had a remarkably uneventful convalescence and lived to be 8 years of age when she succumbed to an accident Postmortem examination showed no recurrence of the original growth nor any abnormality of the remaining thoracic viscera except a compensatory dilatation of the right lung In April 1933 Graham² had performed the first one stage total pneumonectomy for a primary carcinoma of the lung In this instance the patient, a physician, is still alive and actively engaged in practice The series of cases herein reported and that of Graham,³ recently published, not only parallel each other in respect to their approximately simultaneous beginning but also in number, survival time and results, a source not only of great interest and gratification but also of supportive and corroborative data Two series so identical in every respect, built up independently and in different parts of the country and showing essentially the same results must be unique

My purpose in this report is to record the clinical analysis and the results of 181 consecutive cases of primary carcinoma of the lung in which operation has been performed over a period of eleven years Of this total group 71, or 39 per cent, have been operable, whereas 110, or 61 per cent, were inoperable at the time of exploration A large number of patients who were seen examined and rejected for operation because of obvious clinical signs of inoperability are not included

Since 1933 the clinical importance of primary cancer of the lung has been emphasized because of the fact that during these years a surgical technic for the removal of an entire lung has been developed In the years previous to 1933 the physician made such a diagnosis for academic reasons alone because there were no therapeutic methods which offered the patient more than palliation Medicinal and radiation therapy were equally ineffective, and the disease when so treated was always fatal

Surgical treatment of malignant tumors of the lung has been a boon to patients and a lively stimulus to clinicians interested in pulmonary lesions Because of this increased interest on the part of physicians the diagnosis of primary tumors of the lung is made much more frequently than in the past with the result that a greater number of such patients are being referred for operation In certain medical centers in which a special interest in this type of surgery has been manifested what seems a disproportionate increase in the frequency of these cases is apt to occur but it is a fact that the incidence of primary pulmonary cancer is increasing It is not within the province of this clinical report to discuss the probable reasons for this increase except to state that in the series of cases reported the majority of authors agree that the constant inhalation of irritating substances undoubtedly plays an important part Ochsner,⁴ in his inclusive review of the literature, has collected much interesting information on this subject

CLINICAL ANALYSIS

Because of occupational hazards and habits a higher incidence of primary malignant tumors of the lung would be expected in the male than in the female Table 1 shows the distribution according to sex of the patients in this series It is to be noted that there was a much higher incidence in the males than in the females, a ratio of almost 6 to 1 in favor of the males The incidence of involvement of the right and left sides was approximately the same

Table 2 shows the age limits of the series and demonstrates that the age incidence of carcinoma of the lung does not differ to any great extent from the age incidence of malignant growths elsewhere in the body Sixty-four of the patients were in the fourth to sixth decades inclusive Perhaps patients in the second to fourth decades were more frequently affected than would be the case with carcinoma of other viscera, however, this series of cases although relatively large, is far too small to warrant an exact statement Twelve of the cases fell in the sixth decade In this series the oldest patient operated on was 69 and the youngest 19 Age, in itself seemed to offer no contraindication to operation Not infrequently an older patient, from a physiologic point of view, is a far better operative risk than a younger one In this series the older patients were surprisingly unaffected by the operative procedure and, including the patient aged 69, generally had an uneventful postoperative convalescence Pulmonary carcinoma, however, is a disease of advanced age

In table 3 are listed the most frequent signs and symptoms which were found in this series of patients All symptoms or signs which were referable to invasion of contiguous structures by the direct spread of the

growth from the lung or which were due to metastasis in remote organs or structures were excluded. Only those clinical manifestations which were referable to the lung were considered. In 71 per cent of the patients in this series cough was the chief symptom. In a nation of heavy cigaret smokers in which the population sup-

Left side	44%	49%

plying the majority of our patients breathes the polluted atmosphere of cities, cough is almost universal and is due mainly to nonspecific irritation of the respiratory tract. The important point about coughing that should make one suspicious of the presence of an intrabronchial growth is the departure from the normal for any individual. If in an adult "chronic cough" the type of cough changes to a spasmodic productive or nocturnal type or, again, if a person who has heretofore coughed infrequently suddenly begins to be annoyed by a hacking cough day and night attention should be focused on the bronchial tree and the presence of a bronchial neoplasm should be suspected. The development of a cough or changes in the character of coughing can portend an extremely serious condition. Until physicians as a whole as well as the lay public, become more acutely aware of the serious significance of this sign the opportunity for early and satisfactory treatment of pulmonary neoplasms will be denied to many patients. It is to be noted that the outcome in this condition unless recourse is had to surgery, is always fatal.

In 63 per cent of our patients hemoptysis was associated with coughing. This varied from streaking of the sputum to the expectoration of rather copious amounts of blood, up to 6 ounces (180 cc). In the latter group of patients the accumulation of blood in the mouth was preceded by a "gurgling" in the chest on one side which

TABLE 2—*Age Incidence of Cases of Primary Carcinoma of the Lung*

warned the patient of an impending hemoptysis. In our experience copious hemoptysis has usually been associated with the adenocarcinoma type of intrabronchial growth. Unless the x-ray and sputum examinations are indisputably those of tuberculosis or bronchiectasis hemoptysis must be considered to be due to an intrabronchial growth until this has been ruled out by the many types of examination at our command. The burden of proof is on the physician who in any given case states that hemoptysis is not due to a tumor of the

lung. This is true even though a small number of tubercle bacilli may be present in the sputum. Tuberculosis and carcinoma were associated in 2 of the cases in this series. Clinical examinations to diagnose an intrabronchial tumor in no way interfere with the treatment of pulmonary tuberculosis, but if a patient bleeding from a tumor of the lung is observed for months in an attempt to prove the case to be tuberculous in many instances he will have lost his only opportunity for successful treatment. The discovery that the bleeding was originally from a neoplasm will have come too late.

Pain was present in 50 per cent of the patients in this series. Pain arising from an intrabronchial neoplasm must be differentiated from the pain due to direct invasion of contiguous structures. Pain arising from the lung itself is not associated with the respiratory cycle, as is the pain of pleuritis. It is most often described by the patient as a constant dull ache deep in the chest. The frequency with which the actual position of the tumor as shown by roentgenography coincided with the location of the level of pain on the chest wall as indicated by the patient was surprising. In all probability pain does not arise within the tumor itself but is a result of pressure on the bronchial wall. Persistent pain in the chest, in the absence of inflamma-

tory disease or aspiration of a foreign body, should always lead to careful investigation of the respiratory tract. Pain down the arm or in the chest wall so characteristically found in the so-called "superior sulcus" or "Pancoast tumor" is as a rule due to direct invasion of the ribs or the brachial plexus or both. This distribution of pain is considered a very unfavorable symptom from the standpoint of operability.

Loss of weight due to cachexia in advanced cases of carcinoma of any organ in the body, particularly the gastrointestinal tract is well known and obvious, but not so easily understood was a striking loss of weight in 39 per cent of the patients with pulmonary carcinoma. This loss of weight was, of course, due in part to coughing, loss of appetite because of hemoptysis and sputum worry and so on, but the rapid gain of 30 to 50 pounds in a few months after total pneumonectomy for the removal of a relatively small growth remains unexplained.

Fifth on the list of signs and symptoms is hyperpnea, occurring in 23 per cent of the patients. These patients complained of a sudden desire to breathe in deeper breaths not exactly similar to air hunger but approximating this condition. The deep breathing sensation one experiences when breathing carbon dioxide would seem to be similar. This paroxysmal hyperpnea came on suddenly and lasted for a few seconds or a few hours. The mechanism of this respiratory phenomenon is difficult to explain. It may possibly be caused by a plug of mucus occluding a secondary or tertiary bronchus already partly plugged by an intrabronchial neoplasm the bronchopulmonary segment of lung to

which the occluded bronchus is a tributary, thus becoming the site of an obstructive emphysema. Reflex disturbances in the respiratory rate and amplitude are thus set up. With expulsion of the mucous plug the respiratory rate returns to normal. Such unusual changes in the respiratory cycle, even though of very short duration, should excite one's curiosity sufficiently to suggest a thorough examination of the bronchial tree.

Eighteen per cent of the patients had suffered from attacks of pneumonitis associated with bouts of fever and all the signs and symptoms characteristic of pneumonia. It was frequently possible to obtain a history of numerous attacks of so-called "pneumonia" in the recent past. The chief characteristic of these attacks was that they had occurred at any time of the year with apparently no tendency toward seasonal incidence as in the true epidemic pneumonia. Furthermore physical signs were atypical and in unusual locations as regards the lung itself. Lobar pneumonia or bronchopneumonia, as a rule presents fairly typical physical signs. This is not the case in pneumonitis due to bronchial obstruction associated with primary carcinoma of the lung. The explanation for these unusual observations is not far to seek when their pathogenesis is considered. When obstruction of a secondary or tertiary bronchus occurs as a result of a new growth alone or in association with a mucous plug there is filling of the bronchial tree peripheral to the point of occlusion. Eventually infection of this bronchopulmonary segment occurs and the clinical syndrome of localized pneumonitis is produced. A portion of a lobe of greater or lesser dimensions, the entire lobe or even the entire lung may be involved. If exacerbations of such a pneumonitis are of sufficient frequency, bronchiectasis or even an abscess will at times supervene. Often such an abscess perforates into the pleura and produces putrefactive empyema. The point to be emphasized is that when such an unusual sequence of events takes place, or when any one of the aforementioned inflammatory episodes occurs that cannot be explained as a complication of a typical pneumonia or as a result of aspiration of a foreign body, an intra-bronchial growth should be suspected.

Recurrent bouts of unexplained fever unassociated with abnormal physical signs were present in 13 per cent of the patients for some time before the diagnosis of a lung tumor was confirmed. Such an elevation of temperature is in all probability associated with infection in and distal to the involved bronchus.

In general, it may be stated that there are no characteristic signs and symptoms of primary carcinoma of the lung. This lesion masquerades as many of the commoner disorders of the lung. The onset is often insidious, but the recurrent nature of signs and symptoms previously described should call the attention of the patient and the physician to the respiratory tract so that a thorough examination will be carried out. Especially is this true of a patient who has previously had excellent health and in whom after the second decade there develops a cough associated with hemoptysis. Too often precious time is lost because of a diagnosis of pulmonary tuberculosis, lung abscess, unresolved pneumonia, bronchiectasis or heart disease. The methods of examination employed to rule out the presence of an intrabronchial growth in no way interferes with the diagnosis or treatment of any of the conditions which are at times mistaken for such a growth.

DIAGNOSIS

In this series of 181 cases the roentgenogram of the chest was positive in every instance. It is not suggested that a diagnosis of primary carcinoma of the lung could be made from the roentgenographic studies alone, but there was in each case an abnormal shadow which necessitated further study and examination. Thus it can be stated emphatically that in every instance in which roentgenograms of the chest show a departure from normal and in which this departure is not in every way characteristic of one of the commoner lesions of the lung the presence of bronchogenic carcinoma should be inferred. Unquestionably the roentgenogram is the most important and the simplest method of examination at our disposal. Even in the earliest stages of growth of a primary carcinoma of the lung the lesion as a rule can be discovered. In the early part of the last decade it was disheartening to watch an early pulmonary lesion develop over a period of months into an inoperable cancer of the lung because physicians who were not aware of this danger would advise the patient to "wait and see what happens." Sometimes shadows cast by hilar infiltration due to other conditions such as tuberculosis or even normal structures are confusing. However an infiltrating hilar shadow in a patient past middle age associated with cough, hemoptysis and the absence of tubercle bacilli in the sputum almost certainly indicates a bronchogenic carcinoma, most of these carcinomas are located at or near the hilus. The diagnosis of carcinoma of any organ cannot be positively made by x-ray examination alone but the more experienced the observer the greater the likelihood of an accurate interpretation. Particularly is this true of lesions of the chest. Positive roentgenograms may show a shadow produced by the new growth itself or by an area of atelectasis, bronchiectasis, pneumonitis or abscess caused indirectly by occlusion by the growth of a bronchus leading to a bronchopulmonary segment or segments.

In my experience second to the roentgenogram in importance in yielding information which is helpful in arriving at a definite diagnosis is bronchoscopy. In fact either by direct vision or biopsy or both a positive diagnosis of primary carcinoma of the lung can be made only in this manner. In 61 per cent of the patients in this series a bronchogenic carcinoma was seen by this method and a positive biopsy secured. In 39 per cent the bronchoscopy was negative. Graham was able to establish a positive diagnosis in 75 per cent of the cases in his series. Ochsner believes that positive bronchoscopy will parallel hilar involvement in from 70 per cent to 85 per cent of the cases. A pulmonary growth in the periphery or even hilar lesions confined to the upper lobes may be beyond the vision of the bronchoscopist. Valuable information can be elicited by bronchoscopy even when the growth cannot be seen such as fixation or deformity or both due to pressure of any visible portion of the bronchial tree. The presence of blood or purulent discharge from certain bronchi serve as a lead. In this series of cases there have been no untoward results during or after bronchoscopies and in the hands of experts the patients have little if any discomfort.

In my experience bronchography is a useful diagnostic method only to reveal occlusion of a bronchus by a small growth which does not produce a shadow in the roentgenogram. As all the patients in this series had positive roentgenograms it was unnecessary to

resort to bronchography. However, with benign growths and other lesions this diagnostic method has proved useful.

Aspiration biopsy is mentioned only to condemn it as a diagnostic procedure. This method has been found generally uninformative and very dangerous. The danger arises from the fact that cancer cells or infection or both, may be implanted at any point along the path of the withdrawn cannula or needle.

Exploratory thoracotomy should be resorted to far more frequently in the future than it has been in the past. In the presence of suggestive signs or symptoms of a dangerous pulmonary lesion such as primary carcinoma, when it has been impossible to arrive at a definite diagnosis by all the means at our disposal exploratory thoracotomy should be performed at once. No deaths and no complications have followed such a procedure in a series of 25 cases. Incisions into the thoracic cage heal rapidly, and as a rule the patients are out of bed much earlier than those on whom exploratory laparotomy has been performed. If direct observation and palpation do not reveal the true nature of the lesion, excision of the entire area in the lobe should be performed for immediate microscopic examination, and the diagnosis is made as is customary in questionable cases of carcinoma of the breast. If further

discussion of the situation with the patient seems advisable, the clean thoracotomy wound should be closed and the patient returned to his room for consultation. Later in the week the chest can be reopened and the definitive procedure carried out. With good surgical technic and with the proper administration of one of the many light gas anesthetics, such as cyclopropane, such a procedure has practically no danger and is, to say the least, far less hazardous than awaiting positive proof of the presence of cancer of the lung in the form of metastasis. The old idea that opening the thoracic cage as an operation of election is a form of euthanasia must be abandoned. The impression that all primary malignant tumors of the lung are slow growing and are late in metastasizing is incorrect.

PATHOLOGY

The surgical removal of primary carcinoma of the lung in a relatively early stage has brought about changes in our ideas of the origin and nature of the growth of such tumors. In the past practically all the data assembled were based on the autopsy in very late cases when it was impossible, on account of the almost universal involvement of the lung and contiguous structures to determine the nature origin or progress of the growth within the lung. In this series of cases the majority of the tumors occurred at or adjacent to the hilus, the minority in the periphery of the lung. The latter seemed to spread throughout the area of the lung in which they originated by centrifugal growth most of them apparently having arisen in the alveolar lining cells. The hilar tumors, all of which were bronchogenic

in origin, grew grossly in two separate fashions. The one, an intrabronchial tumor arising apparently from the bronchial mucosa, grew into the lumen of the bronchus and toward the trachea. The centripetal tendency of the growth, occluding completely or partly the primary or secondary bronchus, was characteristic. The other type of hilar growth was an extrabronchial tumor which, probably arising in the wall of a secondary, tertiary or quaternary bronchus, would break through the wall and grow along outside of and often completely around the bronchus. This type of growth also showed this centripetal tendency, growing around and about the secondary and primary bronchi and then spreading directly into the mediastinum to involve the structures contained therein.

The clinical course is dependent to a great extent on method of growth. It is, of course, obvious that the intrabronchial type will produce respiratory difficulties, cough, sputum and hemoptysis much earlier than the extrabronchial tumor. The first symptoms caused by the latter method of growth may be, for example, interference with the venous return from the neck owing to involvement of the superior vena cava on the right side, or recurrent laryngeal palsy or Horner's syndrome on the left. Malignant tumors arising in the periphery are as a rule asymptomatic. They may be said to arise in the silent area of the lung and as they do not as a rule produce bronchial obstruction or erode pulmonary vessels the symptoms and signs are usually those dependent on invasion of the pleura and chest wall and, by direct extension, the brachial plexus.

In 70 per cent of the 71 patients on whom total pneumonectomy was performed in this series there were metastases to the bronchial and tracheal nodes. This fact emphasizes the necessity of performing total pneumonectomy with dissection of these regional nodes in order to effect a permanent cure. In the remaining 110 cases that were inoperable, in addition to metastases in the regional nodes the various organs and structures that were the site of metastases are listed in the order of their frequency of involvement: supraclavicular and axillary lymph nodes, liver, pleura, pericardium and heart, contralateral lung, osseous tissue, brain and multiple areas in the skin and subcutaneous tissue.

The histologic structure of the tumors occurring in this series of cases was determined by examination of the specimen removed at operation and also from biopsies performed in the inoperable cases. The microscopic appearance of these tumors made it possible to divide them into two large groups, the flat and squamous cell carcinoma and the adenocarcinoma. In the latter were included the adenocarcinomas, oat cell types and cylindric cell carcinomas. These various examples are thought to be different forms of the same tumor. In fact, the adenocarcinoma type is pleomorphic. Sections of the tumor differ, depending on the region from which they were cut. Rich, however, is of the opinion that the cellular classifications should be maintained until there is more convincing evidence of a common origin. Womack and Graham, on the other hand, believe that all bronchogenic carcinomas in this group as distinct from the flat or squamous cell group originate in a "mixed tumor" of the bronchus, which gives rise to the small round cell and alveolar carcinomas in addition to those in our classification. As shown in table 4, the flat or squamous cell carcinomas comprised 64 per cent of the cases in this series, whereas the adenocarcinoma group included 36 per cent.

The length of life computed on the basis of the microscopic characteristics of the tumor is shown in table 5. Of those patients who survived to be discharged from the hospital as well, but who died at various intervals of time following their departure, the largest percentage 65, had the squamous or flat cell type and lived a greater length of time than those with the adenocarcinoma type, with the exception of 1 patient, in whom a cylindric cell tumor was found, and 1 in whom an oat cell type occurred who lived three years and six months and two years and two months respectively. The patients in the adenocarcinoma group, including the cylindric and oat cell varieties, had a less favorable prognosis than those in the flat cell group. Of the patients who are living, 63 per cent were classified histologically as having tumors belonging to the flat cell type, whereas only 37 per cent were found having those of the adenocarcinoma group. With the exception of 1 patient, who is alive after eleven years, the outlook for those patients whose tumors were of the flat or

squamous cell type seems to be better. This would appear to be fortunate, since the majority of tumors in this series were of this microscopic structure. It will be interesting to note whether or not this histologic distribution will prove to be constant in the future and in reports from other clinics.

TREATMENT

In our present state of knowledge the only efficacious method for treatment of pulmonary carcinoma is by surgical removal of the entire organ together with the regional lymphatic nodes. Medicinal therapy is only palliative and as these tumors are radioresistant, radiation therapy is of no benefit. From an anatomic standpoint the lung lends itself to surgical removal more readily than any other organ in the body, with the possible exception of the breast. From the point of view of the biologic characteristics of primary carcinoma of the lung surgical removal is more apt to be successful because of the relatively slow growth and spread of these tumors as compared with similar tumors in other regions of the body. Finally the remarkable ability and tendency of the contralateral lung to undergo compensatory changes prevents incapacitation of the patient from a physiologic point of view.

It is not within the province of this report to discuss the problems of surgical technic except to state that any operation designed to cure primary malignant tumor of the lung must of necessity consist of total and not partial pneumonectomy or lobectomy. There is no instance with which I am familiar of a

case of indisputable carcinoma of the lung having been cured by partial pneumonectomy or lobectomy.

The final proof of the efficacy of any method of therapy naturally is obtained from a critical analysis of the immediate and remote results. Tables 6 to 9 present a summary of the successes and failures following operation in this series during a period of eleven years. Ninety-five total pneumonectomies have been performed and table 6 presents the type of case in which total removal of the lung is indicated. In this entire group, as shown in table 7 the immediate mortality was 25 per cent. Twenty-four patients died as a result of the operation or from complications resulting indirectly from the operation. The causes of these deaths are summarized in table 8 and will be

discussed later. In Graham's series of 75 total pneumonectomies in which 70 were for carcinoma, there were 21 deaths in the hospital, or a mortality of 30 per cent. Because of the striking similarity in the results both immediate and late in Graham's and this series it is interesting to compare them. Of the 71 cases of carcinoma of the lung in this series there were 15 deaths in the hospital, or a mortality of 21 per cent. It is to be noted that these figures include the early deaths before the technic of anesthesia was worked out to the

degree of perfection that now exists, and that closure of the bronchus in the early cases was far less secure than the method now employed. These points are emphasized in order to explain the rather high mortality of 21 per cent and to point out that it is only reasonable to expect a substantial reduction in the future. The use of the sulfonamide drugs and recently of penicillin has added greatly to the safety of the operative procedure. Mention should also be made of the fact that since physicians now as a rule refer these patients at an earlier stage of the disease, the technical difficulties have been lessened to a considerable degree. As a matter of fact there was a succession of 17 cases in this series with no deaths and another of 23 patients with only 3 deaths or a mortality of 13 per cent. It is interesting to compare this figure with the last 25 cases of Graham's, in which there were also 3 deaths, or a mortality of 12 per cent. With further technical progress an even lower mortality may eventually be

One has survived for nine years, 3 for seven years 1 for four years, and so on. It would seem desirable to call attention to the fact that all these patients, except 1 who was a professional boxer, have been restored to their normal activity in every respect. They have been able to return to their former vocations and even recreations, such as golf, swimming, fishing and hunting. In all except the occasional case, since it has not been found necessary to perform a thoracoplasty, no deformity of the patient's chest is visible. The remaining lung expands to fill the dead space resulting from the removal of the affected organ. This intrathoracic readjustment has been reported in detail elsewhere. If these results, including Graham's and Ochsner's are compared to those obtained from the surgical treatment of carcinoma of the thyroid, breast, esophagus, stomach and large and small intestine, reported over a corresponding length of time (ten years), it will be evident that removal of the lung for primary carcinoma offers a greater probability of permanent cure than the surgical treatment of carcinoma of any other organ in the body.

Forty-four per cent or 31 patients, lived for one month to five years after discharge. The majority of these patients were definitely improved, being relieved of cough, hemoptysis and often extensive pulmonary suppuration with its attendant discomfort and toxic manifestations.

Table 8 shows the number of patients who died as a result of the operation before discharge from the hospital and the cause of death as proved by autopsy. Fifteen deaths occurred in the series of 71 pneumonectomies performed for primary carcinoma of the lung a mortality of 21 per cent. In 7 cases death was due to causes unrelated to the operative procedure, such as pulmonary embolism cardiac failure coronary thrombosis cerebral hemorrhage, pedunculated tumor of the left auricle plugging the mitral orifice, and acute hemorrhagic pancreatitis. If these complications had not occurred the mortality in this group might have been reduced considerably, perhaps almost half. In 24 total pneumonectomies for conditions other than carcinoma that is, tuberculosis and nontuberculous infections, there were 9 deaths or a mortality of 37 per cent. This higher mortality is to be expected because the presence of long standing infections would, of course, increase the technical operative difficulties and at the same time lower the patient's resistance to operation. In this group 2 patients succumbed to massive pulmonary embolism and 1 to an accidental traumatic severance of the anterior branch of the left coronary artery during an unnecessary thoracentesis by an inexperienced operator. It is clear that even this mortality should be reduced somewhat. However, total pneumonectomy for inflammatory lesions of the lung probably will always carry a higher mortality rate than pneumonectomy for carcinoma.

CONCLUSIONS

An otherwise fatal disease, primary carcinoma of the lung, can be satisfactorily treated by surgical removal of the entire organ. Surgical measures short of total pneumonectomy are not efficacious. Postoperative mortality and longevity are at least as good as, if not better than, the postoperative results following the surgical treatment of carcinoma of other organs.

reached. Of his last 30 patients Ochsner lost only 2 in the hospital, a mortality of 6⅔ per cent. Such brilliant results probably could not be obtained in a larger series, but a mortality rate of 15 per cent would seem to be within the realm not only of possibility but also of probability. When the fact is considered that without operation the disease is always fatal, the alternative risk of operation seems small.

The success of the operative treatment of carcinoma of the lung cannot be judged solely by the immediate operative mortality, although of course this figure is of the utmost importance. The proof of the statement that total pneumonectomy is not just another surgical experiment but is an operation which has gained a permanent place in our surgical procedures is to be found in the remote or ultimate results. If the patient is offered the opportunity for a permanent cure without serious handicaps, the operative treatment should be considered successful. These results are summarized in table 9. It will be noted that 25 patients or 35 per cent of those on whom total pneumonectomy was performed for primary carcinoma of the lung are still alive, well and leading active lives. One has survived for eleven years and in this time has raised a family of 2 children besides doing all her own housework. The lesion was adenocarcinoma of the left lung.

CONTINUOUS CAUDAL ANALGESIA

AN INTERIM REPORT

ROBERT A. HINGSON, M.D.

Surgeon United States Public Health Service
PHILADELPHIA

Since the first report to the medical profession two years ago, continuous caudal analgesia has been the subject of much comment in both professional and lay publications. At one extreme is the bitter criticism from those who have made no effort to study the procedure in clinics where it has been used successfully. At the other extreme are euphoric promises made to the public by journalists equally ignorant of the procedure—promises which grossly exaggerate the clinical observations of the originators.

Some physician critics have attributed to the method complications and sequelae properly chargeable to elementary technical lapses on the part of the operator. The physician who attempts the use of caudal analgesia without first seeing it properly performed, who bypasses the coccyx and then punctures the rectum or lethally deposits a dose of local anesthetic into the cerebrum of the unborn baby has not performed continuous caudal analgesia. The physician who injects 100 per cent alcohol by mistake into the sacral canal or who injects hot saline solution immediately removed from the autoclave into the sacral canal is not justified in condemning this technic because of the subsequent paralysis of his patient. Likewise, the physician who walks into the labor room in street clothes rolls up his sleeves without washing his hands and slips on a pair of gloves to insert a needle through improperly cleansed skin into the caudal canal has no right to attribute the ensuing infection in his patient to the technic.

All these complications have occurred and will recur if members of our profession continue to derive their scientific impetus from the popular magazines. It is to avoid such hazards that the following observations are presented to you who are specialists in the field of anesthesiology, to you whose hands safeguard the divine work of controlling pain. Special studies in regional anatomy, physiology, pharmacology, roentgenology and the obstetrics associated with continuous extradural nerve block by means of medication introduced through the sacral hiatus are integral parts of this new technic in anesthesiology.

Continuous caudal analgesia should be administered only by the specialists and the specially trained physicians. It has worked more satisfactorily in clinics fortunate enough to have a physician-anesthetist and an obstetrician working as a team. It has been repeatedly emphasized that this is a technic to be used in well staffed hospitals where the patient is surrounded with the safeguards of adequate antepartum care, oxygen, vasopressor regulators and antiseptic precautions. The hospitals which can provide the services of physician-anesthetist-obstetrician teams working on a divided schedule throughout a twenty-four hour service will become the maternity centers to which parturient women will come in increasing numbers. It is here that infant and maternal mortality and morbidity will diminish to an inconsequential minimum.

This technic in the first three years of its existence has provided 42,000 parturients with comfortable labors and deliveries of babies born without narcotization and anesthesia. In a careful analysis of these data, it has been determined that the average spontaneous breathing time of the baby from the moment the head was born has been thirteen seconds and the average lusty crying time twenty-two seconds. This study compares so favorably with all other forms of pain relief in obstetrics that its significance is self evident. The fetal mortality in this group has been 1.7 per cent as compared with the fetal mortality in the death registration area of the United States of 5.2 per cent. Out of these 42,000 cases there have been sixteen maternal deaths. Six were attributed to obstetric complications, seven to the misuse of caudal analgesia in unskilled hands and three may be considered anesthetic deaths—emphasizing the small permanent hazard to the mother associated with this form of pain relief.

Continuous caudal analgesia in its numerous presentations to the profession through medical literature has never been advocated by me as a panacea for pain in childbirth. I recommend it only as an agent to relieve the distressing pains of progressive and established labor and delivery. I condemn its use for the discomforts of preliminary and early labor.

Parturients in whom fear can be controlled by confidence in the physician and in their surroundings are the ideal ones for the use of continuous caudal and spinal analgesia. Parturients in whom fear is uncontrolled can still be more satisfactorily managed with amnesia and general anesthesia. These facts emphasize that there is no one single method of pain relief suited to every type of case.

Since anesthetists are more concerned with technics, anatomy, pharmacology and sociological aspects of pain relief procedures I shall summarize the recent advances in these branches of the basic sciences concerned with this procedure.

ANATOMY

Anatomic studies have been carried out in eight medical schools from which careful measurements of more than 20,000 sacra have been performed. The anomalies studied have indicated that malformations of the sacrum are more frequent than of any other bone in the body. Dr. Mildred Trotter and her group at Washington University in St. Louis, in an analysis of 5,000 sacra from the anatomic collections of two medical schools, have determined the incidence of the more common anomalies as follows:

- 1 Twenty-two per cent of sacra have accessory apertures in the roof varying in size from 2 mm to 3 cm.
- 2 Eleven per cent of sacra have a bony defect produced by failure of the superior dorsal arches to close.
- 3 Eighteen per cent of sacra have a bony defect produced by failure of the inferior dorsal arches to close.
- 4 Two per cent of male sacra and 0.5 per cent of female sacra in the series studied have no osseous roof to the sacral canal at all.
- 5 Five and five-tenths per cent of the sacra have either an obliterated hiatus or a diminished anteroposterior diameter to the point that introduction of average sized caudal needles would probably result in failure.
- 6 From another study there have been collected 6 cases of hemisacra associated with large sacroceles that projected into the pelvis. All these were diagnosed as ovarian cysts. In several of them laparotomy and removal of the cyst did not reveal the cause of the pathologic condition, all the patients died of meningitis.

In advanced cases of arthritis and in diseases from nutritional deficiency there are oftentimes osseous projections within the sacral canal which resemble the stalactites and stalagmites of subterranean formations. The frequency of these projections indicates the need for further roentgenologic study in cases of unexplained lumbosacral backache.

Bishop has utilized the Caldwell-Molloy subpubic angle roentgenograms of the sacrum to present information of importance to the physician-anesthetist using caudal analgesia.

NEUROLOGY AND PHARMACOLOGY

In numerous medical publications I have already substantiated the pioneer work of Cleland, who was the first accurately to locate the afferent uterine neurology.

In more than 3,000 personally observed and managed obstetric cases I have not found a single case in which a complete block of the eleventh and twelfth thoracic nerves was not accompanied by a total relief of the abdominal cramps of labor. Likewise I have not found a single case in which well established contractions of the uterus did not continue if the level of analgesia was not permitted to rise above the tenth thoracic segment. Thus I have confirmed the natural anatomic dissociation between the motor and sensory components of the uterine nerves. This fact makes possible the clinical application of caudal analgesia in such a manner that the pains of labor are relieved and the cramps of labor continued without interruption.

A third component of uterine neurology should also be considered, namely, the nerve supply to the cervix. The nerve fibers which run to this fibromuscular structure have been determined to be both sympathetic and parasympathetic. The afferent divisions of these nerves transmit the sensation interpreted by the parturient as the intense agonizing crescendo of pain across the lower part of the back.

The efferent parasympathetic components, which are derived from the second, third and fourth sacral nerves, produce a more or less constant contraction of the smooth muscle bundle guarding the cervical os. Thus an anesthetic block of these nerves produces a welcome relief of pain and a relaxation of musculature which in the presence of forceful uterine contractions from above develops into a rapid dilatation of the cervix and expulsion of the baby through the birth canal.

I have determined in more than 2,000 cases that the use of the three chlorides of Ringer's solution will intensify and prolong the action of metycaine on the nerves in the peridural space.

Because of the pronounced vasomotor block with the associated peripheral vascular dilatation, there is produced a hypotension on a purely mechanical basis. Direct observation of the spleen in cesarean section under this type of analgesia reveals that it does not vary in size to account for this lowered blood pressure. Recently this hypotension has been combated in the following manner:

- 1 The use of 50 mg. of ephedrine sulfate as needed
- 2 Elevation of the extremities to right angles with the body in cases in which a fall in pressure develops of more than 20 mm. of mercury systolic
- 3 The use of 100 per cent oxygen inhalations in cases of nausea, hypotension or fetal bradycardia

From the therapeutic indications I have utilized continuous caudal analgesia to produce a hypotension in the preeclamptic, in the eclamptic with convulsions, and

in medical cases with essential hypertension. In all of these cases I have observed striking clinical improvement immediately after the institution of the technic on the basis of the following phenomena:

- 1 Peripheral vasomotor dilatation in the pelvis and lower extremities
- 2 Vasomotor changes in the kidneys with an associated increase in the output of urine

Altogether 42 eclamptic patients in a convulsive state have been relieved of all nervous system symptoms. Of these, 40 have delivered live babies without maternal mortality. In 6 such cases continuous caudal analgesia was utilized with surgical induction of labor by rupturing the membranes. In these labor and delivery progressed with accelerated rapidity.

My experience suggests that this technic in which the nerve block is continued for four to six hours in the treatment of thrombophlebitis, sciatica, intractable pain of pelvic carcinoma, ureteral or vesical colic, Dietl's crisis, burns of the lower extremity, arterial emboli of the legs and peripheral vascular angiospastic diseases should be further investigated in the hands of competent specialists. I have treated more than 200 patients with the listed diseases who have improved, oftentimes dramatically. This technic can also be used as a test index prior to surgical sympathectomy.

In surgery the technic is found to be an indicated method in operations below the umbilicus in the debilitated, aged and cachectic patient who does not tolerate many of the other forms of anesthesia. I have found this technic applicable in the management of industrial and war trauma of the lower half of the body, in which it may be used to control pain for many hours before, during and after surgical and orthopedic operations.

In another report my associates Lull and Ullery have described the use of caudal analgesia in 160 cesarean sections without loss of mother or baby.

Certain improvements in the technic of the production and maintenance of caudal analgesia have been advanced. The malleable stainless steel caudal needle, so successfully used in the last 3,000 cases, has almost eliminated the hazard of needle breakage (with the straight stiff steel or the malleable German silver needle) provided the needle is used in parturients who labor on their sides and provided the needles are discarded after five administrations of continuous caudal analgesia. Lundy and his co-workers developed a substitution technic that was simultaneously but independently presented by Manalan of Indiana, namely, the use of the ureteral catheter. This technic has advantages for parturients who are uncooperative and for those eclamptic patients who have lost their central nervous system motor control. It also is the procedure of choice for certain parturients with large pendulous abdomens who, for obstetric reasons, should labor on their backs.

The continuous drip method of caudal analgesia introduced by Block and Rotstein presented a few useful advantages over the other technics. At the same time new hazards were incurred to the patient. To overcome these hazards Major James L. Siever of Fort Sam Houston, Texas, who has supervised more than 2,000 continuous caudal confinements, introduced the regulated intermittent modification of the continuous drip technic. This refinement consists in the conventional injection of the test dose and the first dose of the

analgesic agent All subsequent doses however are permitted to flow by gravity through a special apparatus that automatically regulates 20 cc doses at a time

The latest modification of technic is my introduction of the nontraumatic nylon needle which is inserted by means of a stiff steel stylet that is withdrawn as soon as the sacrococcygeal ligament is penetrated This needle may be left in for many hours without fear of trauma

Thus I emphasize that continuous caudal analgesia is a new technic, still in the developmental state In its use in the various branches of medicine I implore your caution and solicit your consultation and report

807 Spruce Street

ABSTRACT OF DISCUSSION

DR JOHN G P CLELAND, Oregon City Ore I agree with Dr Hingson that caudal analgesia is definitely a specialized procedure requiring a thorough knowledge of anatomy and physiology, surgical training, equanimity and painstaking care in addition to a good obstetrician with special hospital facilities As an example of what special training and team work will do, witness the record of the Lundy department of the Mayo Clinic with more than 15,000 caudal analgesias (surgical and obstetric) without a death—the largest series of any form of anesthetic at that clinic without a fatality Relative failures may be prevented by secal sodium premedication followed by paravertebral block of the eleventh and twelfth thoracic nerves, which I have proved by hysterographs to permit strong contractions with pain relief to continue until progressive labor has been established, at which period I believe caudal analgesia to be indicated If inability to enter the hiatus has not been foreseen by routine x-rays, and general narcosis and general anesthesia are not desired, paravertebral block repeated at infrequent intervals with nupercaine hydrochloride may be given and delivery accomplished under the pudendal block of De Lee and Greenhill To insure pain relief in obstetrics without interfering unnecessarily with the expulsive powers of the uterus, no matter whether one uses Hingson and Edwards' malleable needle Lundy and Manalan's catheter or Block and Rotstein's or Siever's drip method the main thing is to keep the level of analgesia below the umbilicus and yet to include the eleventh thoracic nerve I have experimental evidence by hysterographs that contractions become weaker if the tenth nerve is involved I have found the catheter method of Lundy and Manalan most satisfactory, but Dr Hingson's announcement of the nylon needle seems to combine the atraumatic during movement advantage of the catheter with the smaller opening of the needle I have found continuous caudal analgesia the anesthetic of choice for extensive gynecologic repair operations, which usually are on poor risks for general or spinal anesthesia, for bladder operations and for tedious operations on the lower extremities

DR H CLOSE HESSELTINE, Chicago From his experience at the Chicago Lying-In Hospital Gready has indicated particular dangers and complications which confront those who contemplate or use this method We found that the method is not a practical one in view of our shortage of doctors and anesthetists Every patient receiving this procedure must have a competent and experienced person or persons from the obstetric as well as the anesthetic and analgesic point of view in constant attendance Dr Hingson mentions that they have used this method in 42 cases of eclampsia with favorable results but did not mention the other therapy used at the time One of the fears confronting every obstetrician in association with delivery of a toxemic patient is the possibility of a vasomotor collapse In vasomotor collapse there is a definite decrease in the output of urine or often an actual anuria J Robert Wilson also at the Lying-In Hospital reduced the blood pressure in toxemic patients by Veratrone (pyrocatechin dimethyl ether) but at the same time there was an appreciable decrease or a complete cessation of urinary output It might be postulated

that this drug had a toxic effect, but the same situation is evidenced in vasomotor collapse Because of this it seems evident that there is great hazard in the use of caudal anesthesia for patients with labile blood pressure It is recommended that Dr Hingson make a study on a far greater number of toxemic patients (a significant adequate number) in all details with respect to physiologic and toxemic stages before giving any endorsements for this therapeutic procedure lest a large number of women lose their lives as the result of complications secondarily superimposed by this method Again as we make medical progress we must first do no harm These observations are stimulating but must be critically confirmed or reputed before offering them to the profession at large I agree with Hingson in his recommendation on the limitations It should be used only on direct indication It cannot be a routine procedure as it is now understood Unless abuses of the method are eliminated, the procedure will be forced into discard Only the skilled and experienced should use it and then only with great caution In over 40,000 deliveries at the Chicago Lying-In Hospital there have been but two deaths attributed to anesthesia and analgesia In the 36,000 reported caudal anesthetics three deaths occurred from misuse and three resulting from the anesthesia Since Hingson condemns its use for discomfort of preliminary and early labor, when is it started? How do you give relief prior to this time?

DR ROBERT A HINGSON U S P H S It was Dr Cleland who first pointed the way to the control of pain in childbirth It took about seven years for Dr Cleland to convince the medical editors of our journals that there was something which really had value I have substantiated Dr Cleland's report in 3,000 cases and without exception he is absolutely correct Therefore I should like to propose that the afferent pathway of the uterus be known henceforth as the pathway of Cleland because across that pathway has come the answer to the riddle that has puzzled physicians for ages I would like to commend the attitude of Dr Hesseltime who has used this method sparingly in the Chicago Lying-In Hospital I am anxious to get this type of questions and report I believe that only in this manner can there be due consideration to the problems involved Dr Hesseltime raised the question of the time we start the caudal analgesia In the Philadelphia Lying-In Hospital, in the last 1,000 cases the longest continuous caudal analgesia was thirteen and a half hours We are not using it for the prolonged period of time that we did The average duration of the analgesia in the uniparous patient has been five hours the average analgesia in the multiparous patient has been three and a half hours Thus we recommend it to relieve the distressing pains of labor and not the discomforts of the induction stages For the discomforts of the induction the obstetrician may use any of the bland methods which have been advocated in the past and which have stood the test of time The barbiturates are good Isonipocaine, one of the latest drugs to be introduced demands consideration Continuous caudal analgesia has spread far too rapidly I still express to you considered caution When used properly it is the best method for the control of pains of childbirth It protects a great majority of patients from fear and the distressing aftermath of narcosis cerebri I would like you to be wary of the reports of those who have personally observed less than 50 cases Those are not the reports that will teach the foundations of the technic or the development of the method in the future Rather these reports are to be looked on as the preliminary learning efforts of the physician With regard to the fall in blood pressure in eclampsia, I agree that further study should be given this method and we are carrying it out in our hospital We now have the consultation of specialists from several medical centers on this problem Perhaps within a few months we will be able to give more complete information However, of all the methods used in the control of hypertension and convulsions, continuous analgesia reduces the pain and relieves the pressure and removes the convulsion more effectively than anything we have ever seen Dr Hesseltime did not mention that the baby who had mental damage was delivered by cesarean section under ether anesthesia

THE USE OF PENICILLIN IN THE TREATMENT OF PERITONITIS

AN EXPERIMENTAL STUDY

Peritonitis is the cause of death of 92 per cent of those patients who die after being admitted to a hospital with the diagnosis of acute appendicitis, according to the results of a survey made in Philadelphia by Bower and his associates¹. Peritonitis is also a frequent cause

of peritonitis in the dog by occlusion of the blood supply of the appendix and the subsequent oral administration of castor oil. The bacteriologic flora of this experimental peritonitis is quite similar to that of peritonitis in man.² In addition, it has been found that the mortality from this type of experimental peritonitis can be reduced from approximately 100 per cent to approximately 50 per cent by treating animals with relatively large doses of sulfanilamide or sulfathiazole.³

EXPERIMENTAL METHOD

Operative Technic—Gangrene of the appendix with a fulminating, diffuse peritonitis was produced in dogs by ligating the blood vessels in the mesentery of the appendix with linen thread and the base of the appendix with umbilical tape under anesthesia, using aseptic surgical technic. Immediately after the operation 50 cc of castor oil was given by stomach tube.

It should be pointed out that the appendix of the dog is considerably larger than that of the human being (fig. 3). This would predispose the dog to a larger inoculum and local area of infection than a similar procedure in man. The castor oil, by increasing the motility of the intestine and the activity of the animal, predisposes to the spread of the local peritonitis and increases the mortality from approximately 50 per cent to approximately 100 per cent.³

Postoperative Treatment—After the operation and the administration of castor oil, each animal was given intravenously 10 cc of 2.5 per cent glucose in 0.45 per cent sodium chloride for each pound of body weight twice daily.

The pulse rate, respiratory rate and rectal temperature were recorded every eight hours. Blood cell studies were usually made daily. No food was allowed during the first three or four days, and the animals were not disturbed except for treatment and observations.

Autopsy was performed on the animals which recovered after treatment with penicillin on the twenty-first postoperative day. All other animals were examined shortly after death.

Bacteriology—Cultures were made of the appendiceal site at the time of the operation, and smears and cultures were made of the

peritoneal exudate at autopsy. Details of technic and significance of the results will form the substance of a later report.

Experimental Design—The animals were selected at random and divided into three groups. One group served as a control. A second group was given the same supportive treatment as the control group, and in addition intramuscular penicillin therapy was instituted one hour after the operation and repeated every four hours until the clinical evidence of recovery was

Fig. 1—A typical postoperative course in an untreated animal

of death in ruptured "peptic" ulcer and penetrating wounds of the abdomen.

Whether the administration of penicillin may provide any hope for a favorable outcome in fulminating, diffuse peritonitis may be readily ascertained by a controlled study in animals. For example Bower and his associates¹ have described a method for the production

present The third group was treated as the second group except that the penicillin therapy was not instituted until twelve hours after the operation

RESULTS

Clinical Findings—The clinical symptoms following an induced gangrene of the appendix in the dog are similar to those observed in appendicitis in man. The temperature and pulse rate are moderately elevated, and vomiting often occurs. Blood examinations show a characteristic leukocytosis with a high incidence of immature forms. When rupture of the appendix occurs, the temperature and pulse rate rise sharply, the abdomen becomes tender, rigid and slightly distended, and the respiration is labored.

Operative Complications—An internal fecal fistula due to the cutting action of the ligature at the base of the appendix was responsible for the death of 28 of the 98 dogs used in this study. Penicillin was not effective at the dosage used when the bowel contents were continuously contaminating the abdominal cavity. Hence these 28 animals were omitted from the two series treated with penicillin and the deaths were considered as due to surgical complications. It should be stated that in most instances the fecal fistula resulted in death from the seventh to the seventeenth day postoperatively. Postoperative pneumonia secondary to distemper was the cause of death of 4 of the 98 dogs. The omission of these two groups of animals was considered justifiable, since we were studying the effect of penicillin on peritonitis and not on internal fecal fistula and pneumonia.

GROUP A Controls No penicillin given—Twenty-five of 27, or 92.6 per cent of the animals in this group, died of a fulminating diffuse peritonitis. The average survival time was fifty-seven hours. A typical postoperative course of a control animal is shown in figure 1. All results are summarized in the table.

GROUP B Penicillin treatment started one hour postoperatively—In 20 animals penicillin treatment was started one hour after the operation. A dose of 100 Oxford units per pound of body weight per hour was administered intramuscularly at four hour intervals to the first 5 dogs. After observing the critical clinical condition of these animals during treatment it was decided that a larger dose would be likely to be more effective in controlling this type of infection. To the remaining animals 150 units per pound was given every four hours for thirty-six or forty hours after which the dose was decreased to a total of 5,000 units every four hours for two or three days and then to a total of 5,000 units every eight hours for two or three days.

All of the 20 animals in this group survived. When they were anesthetized and examined twenty-one days after operation gross evidence of generalized peritonitis was not detectable. A typical protocol of a treated animal is shown in figure 2.

Summary of Results

Procedure	No. of Dogs	Per Cent Survival	Average Hours Survival of Those Dying	Duration of Treatment
Controls	27	7.4	57	None
Penicillin started 1 hour after operation	20	100		7 days
Penicillin started 12 hours after operation	19	79	45	7 days

GROUP C Penicillin treatment started twelve hours postoperatively—This group was designed to ascertain the effectiveness of penicillin after the infection was

Fig 2—A typical postoperative course in a treated animal. Ten thousand units was given every four hours for four and a half days, then 5,000 units every four hours for one day and then every eight hours for three days.

well established. Accordingly, the treatment was not started until the twelfth postoperative hour, at which time definite evidence of abdominal rigidity appeared.

The animals received penicillin according to the plan outlined for those in group B. Four of the 19 animals in this group died, yielding a mortality of 21 per cent. It is possible that a larger initial dose of penicillin would have prevented these deaths.

COMMENT

It is evident from this study that penicillin if given early in adequate dosage will completely control uncomplicated experimental peritonitis in the dog. Since this peritonitis closely resembles that found after rupture of the appendix in man, it seems reasonable to assume that adequate amounts of penicillin will have a favorable

chemotherapeutic effect in the treatment of peritonitis in man. From the results of the group in which the therapy was delayed for twelve hours after the appendiceal ligation, one may predict that the longer penicillin therapy in peritonitis is delayed the less favorable will be the results.

It should be noted that on the basis of body weight relatively large doses of penicillin were used in these experiments. It would seem to be certain that, in the treatment of a fulminating, diffuse infection of the type produced in this study, large initial doses of the antibiotic would be necessary. This is indicated by the loss of 4 animals when treatment was delayed for twelve hours and when the animals were given only the dose

Fig 3—Blood supply of appendix

which saved all animals when given one hour after the onset of the infection. Thus, the results of these experiments indicate that large doses of penicillin should be given initially in generalized peritonitis. How large the dose should be for man will have to be determined clinically. If one calculates the dose that might be required on the basis of equivalent body weight, a 150 pound (68 Kg) man with a diffuse peritonitis should receive 22,500 units per hour, or approximately $\frac{1}{2}$ million units per day. If the therapy is initiated before rupture of the appendix occurs, smaller doses might be effective, but if the signs of diffuse peritonitis are present larger doses than $\frac{1}{2}$ million units may be required. Since the large doses of penicillin used in these experiments failed to produce evident symptoms of toxicity, and since no serious symptoms have been described after "massive" doses in man,⁴ it would appear that very large doses are innocuous, especially when considered in relation to the critical nature of a fulminating, diffuse peritonitis.

While penicillin therapy cannot be considered to be a substitute for early surgery based on sound surgical judgment, there are numerous instances in which such therapy may be indicated. Some of the most obvious are (a) operations in which peritonitis is encountered or localized abscesses are inadvertently broken into, (b) those operations on the large bowel or other portions of the intestine in which some degree of soiling of the

peritoneum frequently occurs (c) following gunshot wounds or traumatic injuries to the abdomen, such as underwater blast, and (d) the possible use in the fleet aboard small ships or submarines and at isolated posts where adequate surgery is not available.

SUMMARY

1 A fulminating diffuse type of peritonitis was produced in dogs by ligating the appendiceal base, mesentery and the blood supply.

2 The mortality rate in a series of 27 untreated dogs was 92.6 per cent and the average survival time was fifty-seven hours.

3 There were no deaths from peritonitis uncomplicated by fecal fistula in a series of 48 dogs in which penicillin treatment was started one hour postoperatively. Twenty-eight dogs, however, that developed fecal fistulas died under penicillin treatment.

4 In a series of 19 dogs in which the initial treatment with penicillin was delayed for twelve hours the mortality was 21 per cent.

CONCLUSIONS

1 Penicillin is a remarkably effective agent in the treatment of peritonitis induced in dogs by ligation of the appendiceal base and occlusion of the blood supply.

2 For the treatment of peritonitis in man penicillin should prove to be effective as a therapeutic adjunct to surgery in the treatment of battle wounds of the abdomen and appendicitis and its complications.

3 Penicillin should prove to be invaluable for the treatment of these conditions aboard small ships or submarines and in isolated units ashore where adequate facilities for immediate surgical procedures are not available.

AN EVALUATION OF RADIATION IN THE TREATMENT OF CARCINOMA OF THE CORPUS UTERI

JAMES A. CORSCADEN, M.D.

NEW YORK

During the past three years three out of five and in the latest group all the candidates for the National Board certificate, when asked by me for the treatment of cancer of the corpus, gave hysterectomy as the only method. If the teaching received by these students is reflected in these answers, it is at variance with the practice and published reports of most of those particularly interested in the development of treatment for this disease, who with few exceptions give radiation an important role in the treatment of both operable and inoperable cases. In view of this apparent discrepancy between precept and practice, it seems important that the therapy of cancer of the corpus be reviewed until the merits of the various procedures become established. While with few exceptions all agree that hysterectomy, if feasible, should be performed at some time, some operators question the value of radiation. This study is an attempt to answer this question and, since in the treatment of inoperable cases there is no disagreement, will consider only operable cases, approaching the matter from the clinical, pathologic and technical standpoints.

From the Department of Obstetrics and Gynecology, Columbia University College of Physicians and Surgeons.
Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

⁴ Lyons C. Penicillin Therapy of Surgical Infections in the U. S. Army, J. A. M. A. 123:1007 (Dec 18) 1943.

From the clinical standpoint a precise appraisal of the results of any given form of therapy is made difficult by the relatively small total of cases reported which have been treated by any one method, by the fact that the reports cover the work of half a century during which technics, especially in the case of radium, have been more or less altered by differences in clinical and pathologic standards and by the different standards of reporting some results being based on totals of treated cases and others only on cases which have been followed. I shall give figures from the literature, attempt to interpret them and present our experience at the Sloane Hospital.

Hysterectomy alone for carcinoma of the corpus promises at the present time a five year survival of somewhere near 60 per cent. The term "hysterectomy" practically always signifies a bilateral salpingo-oophorectomy and complete abdominal hysterectomy without dissection of the paracervical tissues or the pelvic lymph nodes. The results given in table 1 represent those obtained during the past forty years. They may be bettered somewhat by the lowering of the operative mortality and possibly by some improvement in the general level of operative efficiency, but they represent the work of master surgeons employing the same general technics as are practiced today. Other series have been reported such as those collected by Morton¹ and Arneson,² and give favorable results as high as 78 per cent, but in small groups of cases. Averaging these results and making allowances for statistical variability, it seems probable that a patient operated on today may be given a safe prognosis of about 60 per cent. Vaginal hysterectomy has given a somewhat lower figure.³

Hysterectomy aside from the operative mortality, which is gradually being reduced, and cases in which distant metastases were present at the time of operation about which nothing at present can be done, fails in some cases because of recurrences in the vaginal or abdominal wound, evidently, especially those in the abdominal wound, from implantation of live cancer cells spilled during the operation. It also fails almost completely to eradicate growths of the anaplastic type. Mahle⁴ stated that he had seen none of this type cured by hysterectomy, and all authors report a very low survival rate.

Radium without operation, when employed in operable cases, promises a five year salvage of better than 50 per cent. Table 2 represents the results of this type of treatment from the beginning to the present. Other series reported by various authors, Norris and Dunne,⁵ Ward,⁶ Miller,⁷ Brindley,⁸ Masson⁹ and Arneson,² combine the results obtained in both operable and inoperable cases and indicate an over all average five year salvage of 39 per cent. Since I am considering the care of the operable case, these figures will be considered no further. Operable cases in which radium

has been administered have been mostly of the "technically" operable class suffering from general conditions which contraindicate any severe operation. Only Heyman⁹ has treated any considerable number of "clinically" operable cases.

To obtain a figure on which to base a prognosis for a patient to be treated today, we must scrutinize sharply the figures in table 2. These results have followed the use of radium from the earliest halting and experimental attempts down through to the present. And even now the technic of radium installation is far from standardized. Despite the warnings of Sampson¹⁰ in 1934 of the inaccuracy of the tandem and the apparently demonstrated superiority of the packing technic, many physicians continue to employ the simple tandem and to give doses too small to be effective. To illustrate the difference between the old and the new, Heyman⁹ compares his results obtained from 1914 to 1931 with those from 1932 to 1935. In clinically operable cases results climbed from 42.9 per cent (in 84 cases) to 62.8 per cent (in 94 cases), in technically operable

Sloane Hospital (this study)		

cases from 33.3 per cent (in 102 cases) to 50 per cent (in 64 cases) and in inoperable cases from 16.7 per cent (in 42 cases) to 40 per cent (in 20 cases).

In the opinion of all authors there is found a correlation between the clinical extent of the disease and the salvage rate. Our cases, when the uterus was smaller than that of an eight weeks pregnancy 6 of 8 patients (75 per cent) survived five years, when the uterus was larger than this but operable, 7 of 19 (37 per cent), when the carcinoma had spread beyond the uterus, of 21 only 1 survived (5 per cent).

Concerning tissue grading there is a divergence of opinion. Healy¹¹ found typing in their irradiated cases of less significance than in those treated by hysterectomy. Reuterwall¹² in 680 cases found no relationship between the microscopic picture and the clinical results of radium therapy and Miller⁷ observes that tissue grading does not affect the treatment. On the other

hand Fricke and Heilman,¹³ Arneson² and Bowing and Fricke¹⁴ found a distinct difference between the clinical results in differentiated growths and those of the anaplastic type. The prevailing opinion is that tissue grading is of less importance in cases treated by radium than in those treated by hysterectomy.

In summary there has been in the past, following radium application to operable carcinoma of the corpus, a salvage of an average of 49 per cent. In the future, with the technics of today, we may promise a five year salvage of 55 per cent.

X-rays alone have seldom been employed for cancer of the corpus. Wintz¹⁵ reports a five year salvage of 69.1 per cent of 127 operable cases and 17.9 per cent of 134 inoperable cases, a result achieved by no one else. Gibert and Solomon¹⁶ have never seen a case so cured, and Merritt¹⁷ states that "it has been our experience over a period of twenty years that radiation alone cannot be relied on for the treatment of corpus cancer." Direct evidence of the effects of x-rays in our clinic is scattered. In 1 case a massive pelvic extension from a corpus carcinoma was treated by

done. Of 7 not receiving postoperative x-rays only 1 patient survived five years, while in 14 receiving the treatment 6 survived. Masson,³ who "only advised postoperative irradiation when the growth was found to be of a high degree of malignancy or when it had extended well into the myometrium," in 194 such cases had a five year survival of 67.5 per cent and a ten year survival of 61.2 per cent, while in 306 cases presumably with a less serious condition, because they were treated by hysterectomy alone, he had a five year survival of 66.6 per cent and a ten year survival of 54.5 per cent.

Preoperative x-rays without radium, employed by Miller,⁷ gave a five year salvage of 70.5 per cent, corrected for noncarcinomatous deaths, 82.3 per cent. In conjunction with preoperative radium, Schmitz,¹⁸ employing 800 kilovolts, reports apparent improvement in results, as does Healy,¹¹ employing 200 kilovolts.

My general conclusion is that x-rays have a definite cancericidal effect and, while at present incompletely effective when used alone, should be considered as essential in the treatment of corpus carcinoma.

Combined preoperative radium and hysterectomy have in the past given a five year survival of 70 per cent (table 3). In our own 25 cases there was an operative mortality of 80 per cent (pulmonary embolism 1 case and a case of hyperthyroidism with cardiac failure which at the present time would be treated entirely with radiation). There was one noncarcinoma death peculiarly caused by an "inflammatory" carcinoma of the breast definitely unrelated to the uterine growth. There were four deaths from generalized metastases. In all of these patients the growth at the time of the operation had extended into the parametrium or adnexa, in 2 cases to such an extent that they should be classified possibly as inoperable. There was no recurrence in either the abdominal or the vaginal wound. Interestingly, in none of those who survived five years was there any extension beyond the uterus.

The five year prognosis from the combined therapy applied according to present day standards should approach 80 per cent. Operative mortality should be reduced by the improvements in the management of shock and infection and by elevation of the general level of operative efficiency. Radium technic in the older cases was helter skelter. Dosages varied from 1,200 to 6,000 milligram hours. Healy¹¹ in 93 cases treated by all doses had a five year survival of 55 per cent and with doses of 3,000-4,000 milligram hours, one of 75 per cent. The improved results following the packing technics should be apparent here as in the cases treated by radium alone. The x-rays employed in the treatment of the older cases were less varied, but even here, following the employment of higher voltages, an improvement in results is expected.

The superior results of the combined preoperative irradiation and hysterectomy may be explained by the fact that the deficiencies of each method are met to some extent by the other. The metastases in the abdominal and vaginal wounds are eliminated by the caustic action of the radium. The high fatality rate following hysterectomy for anaplastic carcinoma will be lowered by the specific cancericidal effect of radium and x-rays. On the other hand the carcinoma remaining in the uterus and adnexa after radium treatment will be

TABLE 3—Carcinoma of the Corpus Uteri. Five Year Survival Rates Following Radium Followed by Hysterectomy

	Treated	Survived

x-rays (700 kilovolts, total of 10,200 roentgens through three ports) after an attempt to insert radium was abandoned because the ulceration within the uterus had extended to the rectal wall. The parametrial involvement disappeared. Twenty-one months later radium was inserted into a grossly normal uterus and fifteen months later applied to a recurrence in the vaginal wall. The patient is symptom free, with no sign of carcinoma five years after the first treatment and one year after the last radium application. In another case a mass 2 cm. in diameter appearing in the abdominal wound two months after hysterectomy for a vicious anaplastic carcinoma of the corpus, was treated with 200 kilovolts along with routine postoperative therapy. The patient has remained well five years. In a third case in which operation was performed for a large ovarian mass which turned out to be secondary to a small carcinoma of the corpus, a recurrence in the pelvis appeared six months after operation, reached the size of a four months pregnancy, was treated by x-rays and shrank to a diameter of 4 cm. in four months. These cases are not presented as "cures" but as evidence of a definite cancericidal effect of x-rays.

Indirect evidence of the effect of x-rays on carcinoma of the corpus is offered by 21 cases of carcinoma of the corpus in which supravaginal hysterectomy was

removed by the operation. Unfortunately in our cases, if it had extended outside the uterus, it had already become generalized.

From the pathologic standpoint there is ample evidence of the effect of radium on carcinoma of the corpus. An opportunity to study these effects is afforded by specimens removed by hysterectomy after intrauterine application of radium. The 70 specimens indicated in table 4 (64 from Sloane Hospital and 6 from the Englewood, N. J., Tumor Clinic) were removed from one to twenty weeks after treatment. The radium had been applied in a tandem or by a device which holds five to seven 10 mg. tubes of radium on the ends of spring wires in such a fashion as to spread them out fanwise in the uterine cavity. The filtration was 1 mm. platinum and 1 mm. rubber. The dosage varied from 1,200 to 5,000 milligram hours.

The carcinoma had completely disappeared in 24.3 per cent of the cases. In 35.4 per cent there was a severe but incomplete destruction of the cancer. Small areas a centimeter or less in diameter contained glandular structures, some obviously malignant, others showing no morphologic evidence of carcinoma but cytologically malignant, and still others so nearly normal that they may have been residual endometrium but because of the original condition were called carcinoma. In 30 per cent there was deep infiltration of the uterine muscle. In these areas there was much less evidence of radiation effect. The architecture of the carcinoma was preserved and the nuclei and cytoplasm of the cells showed little evidence of degeneration.

Among the 70 specimens there were 10 in which there were gross or microscopic metastases, in the ovary (8), tube (6), mesosalpinx (1), broad ligament (1) and parametrium (2). The microscopic sections of these metastases showed no radiation effects.

Examination by others of similar specimens shows a similar destructive effect. Healy and Brown¹¹ found complete regression of the tumor in 28 of 69 specimens and a definite correlation between dosage and effectiveness. Farrar¹⁹ found the cancer destroyed in 6 of 27 specimens following doses of 2,000 to 3,000 milligram hours. Donovan²⁰ 5 of 46, Martin²¹ in 3 of 4 cases treated by 3,000 to 4,500 milligram hours and Schmitz²⁴ in 4 of 5 cases treated by 6,000 milligram hours of radium and x-rays (800 kilovolts).

In summary, one is struck by the apparently localized effect of the radium. The areas of slough and cellular degeneration were limited in area and depth, giving the impression that they corresponded to the location of the applicators. The superficial structures were profoundly affected, areas in the muscle less so and the metastases in the ovaries not at all.

There was no significant correlation between the degree of destruction and dosage or cell type except that carcinoma persisted in all cases in which less than 2,000 milligram hours was given.

From the technical standpoint the gynecologist will be surgically equipped and will refer patients to the proper experts for x-ray therapy but will in most instances be called on to insert the radium unless he

is a member of a highly organized clinic. It therefore behooves him to perfect himself in this technique. This is still in a state of development, which however has yielded two principles. Dosage must be adequate and the uterine cavity must be uniformly irradiated. The dose prior to operation must be from 3,000 to 4,500 milligram hours if given in one massive dose. If small amounts such as 50 mg. are inserted, they may remain for a maximum of one hundred hours. This will cause a sharp reaction, resulting in congestion sufficient to cause considerable oozing at an operation performed six weeks later. With the applications further prolonged by repeated insertions spread over two weeks, doses as high as 6,000 milligram hours have been given.¹⁸

The method of applying radium should be such as to cover the whole endometrial cavity. By packing the uterus with 8 mg. radium units in applicators of different sizes Heyman⁹ improved greatly his results, as already indicated. Arneson,²² by the use of gauze strips, Crossen,²³ by placing small units in a continuous thin walled tube, and Martin,²¹ by the use of hinged applicators, accomplish the same thing. Mechanical devices for spreading out the radium are employed by Schmitz,²⁴

Friedman²⁵ and Strauss²⁶. The elasticity afforded by packing with individual units seems to assure a more thorough and even distribution of the radium.

SUMMARY AND CONCLUSIONS

In the treatment of operable carcinoma of the corpus, hysterectomy, radium and x-rays all are essential. Hysterectomy, which alone promises a five year survival of 60 per cent, fails in a certain number of cases because of recurrences in the abdominal and vaginal wounds and is almost completely ineffectual for anaplastic carcinoma. The first of these is corrected by the caustic action of radium, which, when complete, prevents the spilling of live cancer cells and the second to some extent by the specific action of radium and x-rays.

Radium alone promises a five year survival of 55 per cent but, because of its distinctly local effect, fails to destroy cells lying deep in the myometrium and in metastases in the adnexa. Hysterectomy, by removing such residual tumor tissue as is limited to the pelvic organs, overcomes this deficiency.

It seems therefore logical to employ all these methods. When this has been done there has been a five year

survival rate of 70 per cent by all sorts of technics. The employment of present day technics promises a five year survival of 80 per cent.

In technically operable cases irradiation promises a five year survival of 50 per cent.

180 Fort Washington Avenue

ABSTRACT OF DISCUSSION

DR LEWIS C SCHEFFEY, Philadelphia. During the last decade much has been added by the preliminary irradiation of the patient with fundal carcinoma. We had been disappointed by the low survival rate of patients who had been treated primarily by total hysterectomy and the removal of the tubes and ovaries for carcinoma of the fundus so during the past ten years we have employed a routine technic of diagnostic curettage in a suspected case, at which time an adequate amount of radium is available for intrauterine application. The curettings are examined by a rapid four hour method and if we find adenocarcinoma, irrespective of the grade of the tumor, an adequate dose can then be administered, arranged with regard to the contour of the fundus. Enough irradiation is thus provided for a dosage anywhere between 3,000 and 5,000 milligram hours. If, on the other hand, the lesion is benign, we can depend on a suitable dosage of radium for the treatment of that particular patient. Following the adoption of this plan of therapy, our survival rate rose from 43 per cent a few years ago to 53 per cent. Therefore I believe that this method is superior to that of immediate hysterectomy for carcinoma of the fundus. Some gynecologists, notably Normal Miller, favor the use of external irradiation primarily. If, when hysterectomy is performed six to eight weeks later, one finds evidence of extension of the disease beyond the uterus, postoperative external irradiation should follow. In all the uteri that we have removed we have found residual carcinoma in 50 per cent of the cases. That teaches us two lessons. First never depend on the radium solely if the patient is at all operable, secondly, in the inoperable or poor risk patient at least a 50 per cent recovery may be offered with irradiation alone. In women of the premenopausal and menopausal groups who are bleeding (patients of the type discussed by Dr Randall), supravaginal hysterectomy is too often performed, based on the assumption that the pathologic condition present is due to fibroids. Actually a total hysterectomy should be carried out because of the possibility that carcinoma may be present in the endometrium as an accompanying lesion.

DR H E SCHMITZ, Chicago. I have recently published a study of carcinoma of the uterine fundus treated with radium and x-rays. These cases were treated much according to the technic as described by Dr Scheffey. At the time of the original curettage, an adequate dose of radium was inserted into the uterine cavity. After the diagnosis had been microscopically confirmed, the treatment was continued until the patient was given, in divided dosage, 6,000 milligram hours of radium and a total of 4,000 roentgens of x-rays into the tumor. At intervals of from six weeks to three months I removed these uteri, cut them into blocks and took multiple sections of each block. I would cut a section, cut down ten or fifteen, and take the second section. From each block there were from seventy-five to one hundred and fifty slides. It was concluded that no matter what the grade of the adenocarcinoma, if it was superficial, limited to the endometrium or just beginning extension into the myometrium, it was destroyed by this treatment. However, if there had been extension into the myometrium the findings were like those of Dr Corscaden namely that the carcinoma within the myometrium or the deeper tissues showed little radiation effect. I feel therefore, that preoperative irradiation adds something to surgery but the question is as to whether or not this period of delay is in some way a contraindication to the employment of preoperative irradiation. If we have a superficial adenocarcinoma then, of course the treatment has been adequate and surgery can be done at any time without any difficulty. However, if this carcinoma had extended into the myometrium

and there was little radiation effect then possibly this two or three month delay, which is necessitated by the extreme reaction to that amount of irradiation may contraindicate this method of treatment.

DR CLYDE L RANDALL, Buffalo. All of us who have given radium treatment for menopausal bleeding in what we thought to be adequate dosage to stop all ovarian activity have been sometimes surprised that we apparently failed to stop all ovarian activity, because the woman later develops functional bleeding. That is particularly true if an intrauterine dosage of 1,000 to 1,200 milligram hours is used. I do not believe that is adequate to castrate the woman effectively, certainly it is not sufficient in all cases. Urologists have found, in attempting to stop the androgenic stimulation to metastatic foci of prostatic carcinoma that it is necessary to do an orchiectomy, since no amount of irradiation to the testis proves capable of stopping all androgenic activity. It seems possible, therefore, that at least some women who have had radium for menopausal bleeding could have some follicular activity several years later. Clinical evidences of deprivation of estrogenic hormone and not the history of irradiation alone should be regarded as evidence of preexisting castration. With such evidences of castration present I do not believe that adenocarcinoma in the uterus will be found.

DR JAMES A CORSCADEN, New York. One of the most important points presented was that of Dr Schmitz—the penalty of delay. Two or three months is a long time for a cancer to remain free to metastasize. The only answer I have is that a woman treated by hysterectomy has a 60 per cent chance of surviving five years. A woman treated by a combination of radiation and hysterectomy has somewhere between 70 and 80 per cent and that is not too high. The words "efficient technic" have been mentioned several times. There are two phases—one is dosage and the other the manner of application. In our specimens there was no carcinoma treated by 2,000 milligram hours of radium or less in which the cancer did not persist. In any form of treatment, rapid or slow, it is perfectly safe to give from 3,000 to 4,000 milligram hours of radium that is to say 200 mg for twenty hours or 100 mg for forty hours. That I would call massive treatment. I use 50 milligram hours of radium for a maximum of one hundred hours, making 5,000 milligram hours. With this dose there will be a good deal of congestion at the operation performed six weeks later, making it somewhat easier except for increased oozing. Dr Schmitz carries his procedure still further, up to two weeks by multiple application, giving as much as 6,000 milligram hours. About the manner in which the radium is applied, the technic should be such as to spread the radium evenly throughout the uterus. In the technic here employed, the applicators on the ends of wires were placed about a centimeter apart. The specimens show slough beneath the applicators and viable carcinoma in the areas between. A better technic is the packing of the uterus as employed by Heyman, Bronson and Morton. Mechanical devices of Schmitz, Strauss and Friedman are excellent but do not have the elasticity of the packing technic. Referring to the paper of Dr Randall to guarantee amenorrhea in a woman in her forties 2,000 milligram hours of radium is necessary. Even then irradiation will be necessary in some 2 per cent of the cases. With doses of 1,200 milligram hours there will be a return of menstruation in something like 8 per cent.

Syphilis as an Infectious Malady—Jean Astruc (1684-1766), physician to Louis XIV of France, was first to recognize syphilis as an infectious malady. Among other things he said "and therefore it is by no means strange that many of the Neapolitans should be infected with the same distemper, since they served under the same colors and had to do with the same women who followed the camp. The same towns were taken and reconquered by both parties, 'tis plain that the French must also have had communication with the same women who had lain with the Spaniards and the Neapolitans, and thus the siege of the venereal disease must have naturally passed from one to another"—Gordon, Benjamin Lee. *The Romance of Medicine*. Philadelphia: F. A. Davis Company, 1944.

AORTECTOMY FOR THORACIC
ANEURYSMJOHN ALEXANDER, M.D.
AND
FRANCIS X. BYRON, M.D.
ANN ARBOR, MICH

On Oct 20, 1943 we successfully removed an aneurysm of the thoracic aorta measuring 11 by 8 cm, together with a 7.5 cm length of the aorta. We are reporting this case because of its historical interest from the physiologic, medical and surgical points of view, since we can find no record in which an aneurysm of the thoracic or abdominal aorta has been successfully removed or in which the thoracic aorta has been successfully ligated.

Kummel¹ reported in 1914 that he had resected a fist sized aneurysm of the lower thoracic aorta and closed the 10 centimeter long defect in the aorta with two rows of continuous sutures, hemorrhage having been controlled during this phase of the operation by a twelve minute digital compression of the aorta both above and below the aneurysm. After the operation pulsation was good in the lower extremities but the patient soon died "in collapse."

Both Kummel² and Sauerbruch³ state that Tuffier resected, or attempted to resect, aneurysms of the thoracic aorta in 4 patients by clamping and dividing the neck of the aneurysm and oversewing the stump. Sauerbruch states that 1 patient died of secondary hemorrhage, 1 died from surgical hemorrhage after the stump slipped out of the clamp, 1 died seventeen days after operation during which the aneurysm ruptured and was tamponaded with India rubber, and 1 died after failure to isolate the neck of the aneurysm. In Tuffier's writings we have been able to find reference to only 1 case,⁴ in which the neck of a saccular aneurysm of the ascending portion of the aortic arch was doubly ligated with catgut, the aneurysm itself could not be dissected free and removed, the patient died from hemorrhage thirteen days after operation and the aneurysm was found to have become necrotic.

We have been able to find only 3 records of complete ligation of the thoracic aorta and two records of partial ligation, all 5 having resulted in death. In 1904 Guinard⁵ completely ligated the lower thoracic aorta for an aneurysm of the aortic arch, the patient died three days later from renal insufficiency. Reid⁶ completely occluded the lower thoracic aorta for an aneurysm of the upper abdominal aorta, the patient died twelve hours later from hemorrhage from a divided intercostal artery. Andrus⁷ doubly ligated and divided the lower thoracic aorta for an aneurysm of the abdominal aorta, the patient died an hour and a half later from

shock. Halsted⁸ partially ligated the lower thoracic aorta with an aluminum band for an aneurysm of the upper abdominal aorta and twenty-three days later partially occluded the abdominal aorta distal to the aneurysm; the patient died eighteen days after the second operation from rupture of the aneurysm. Heuer^{9a} partially occluded the lower thoracic aorta with an aluminum band for an aneurysm of the upper abdominal aorta, the patient died one month and nine days later from rupture of the aorta where the aluminum band had been placed.

There are 30 published records of ligation of the abdominal aorta, mostly for syphilitic and nonsyphilitic aneurysms and gunshot wounds. Eight of these ligations may be considered as successful but only in the sense that the ligations were apparently neither directly nor indirectly the cause of death of the 5 patients who had died at the time of the last reports, the word "successful" as used here does not necessarily refer to the effect of the aortic ligation on the lesion for which the operation was performed. It is an important fact that in all these 8 cases the aorta was ligated below the level of the renal arteries. Reid⁶ however (in a case we do not include among the successful ones), completely ligated the aorta above the celiac axis three months after he had partially ligated the aorta below the renal arteries, the patient lived for a month and a half, when a newly formed aneurysm ruptured, during life the circulation in the legs remained good but the autopsy report does not mention whether or not reestablishment of the aortic circulation had occurred at the site of ligation.

Four of the 8 successful ligations of the abdominal aorta (Hamann,¹⁰ Matas,¹¹ Brooks¹² and Bigger¹³) were complete but there was subsequent partial or complete reestablishment of the aortic lumen in all but Brooks's case. In Bigger's case, following ligation of the aorta a second operation was carried out in which both iliac arteries were ligated and an endoaneurysmorrhaphy was performed. In the remaining 4 successful cases of ligation of the abdominal aorta the lumen was deliberately not completely occluded by the ligature (Vaughan,¹⁴ Watts,¹⁵ LaRoque¹⁶ and Elkin¹⁷). Articles by Bigger¹³ and Elkin¹⁷ consider the problems of aortic ligation in considerable detail.

had been x-rayed on December 10 by Dr Vernor Moore of Grand Rapids, who had made a diagnosis of mediastinal mass and probable coarctation of the aorta.

When seen at the University Hospital the patient's chief complaint was fatigue, which had been present since the onset of 'flu,' contracted three weeks previously and characterized by chills, slight fever and generalized aching. His physician noted a persistently rapid pulse and elevated blood pressure and for this reason an electrocardiogram and chest x-ray film were obtained. The patient had always been normally active, his only serious illness having been scarlet fever at the age of 10 years. He was well developed and nourished. A loud blowing systolic murmur, audible throughout the chest, was best heard over the pulmonic valve area. Blood pressure in the right arm was 160/72. It was not obtainable in the legs. Pulsations of the intercostal and internal mammary arteries were palpable. The femoral pulsations were weak and those of the dorsalis pedis arteries were only questionably palpable. X-ray examination of the chest showed an ovoid mass, 6 by 8 cm, which was situated at the left border of the mediastinum at the level of the 5th, 6th and 7th vertebrae and which did not pulsate. There was erosion of the inferior borders of the 4th to 9th ribs bilaterally. The blood Kahn reaction was negative.

those in the aorta below it were only questionably palpable. The aorta at its junction with the upper end of the aneurysm appeared to be slightly constricted. The subclavian, internal mammary and upper intercostal arteries were greatly enlarged.

Since the aneurysm and the aorta at the corresponding level constituted a single chamber (there being no true pedicle of the aneurysm) and since the wall of the aneurysm was very thin, resection of the aneurysm and reconstruction of the aorta did not seem advisable. Cotton tapes, 1.3 cm in width, were placed around the aorta above and below the aneurysm. When these tapes were temporarily tightened there was no definite change in the dorsalis pedis artery pulse, which, as before operation, was inconstantly palpable.

As the thin walled aneurysm was in danger of rupture at any time and as the collateral circulation appeared to be adequate, resection of the aneurysm was decided on. The aorta just below the origin of the left subclavian artery was ligated with a 1.3 cm wide cotton tape, and a silk ligature was placed between the tape and the place where the aorta was to be divided, the aorta approximately 4 cm below the aneurysm was similarly ligated. Three pairs of greatly enlarged intercostal arteries which emerged from the aneurysmal sac were ligated and then the entire aneurysm bearing segment of the

Fig 1—A, anteroposterior view on Dec 10 1941 the tumor did not pulsate on fluoroscopic examination. B, appearance on Oct 19, 1943 the tumor had increased considerably in size during the twenty-two months since A and still had no pulsation. C, lateral view Oct 19 1943 the position and circumscription of this nonpulsating tumor suggest a neurofibroma.

The patient was next seen on Oct 17, 1943 at the request of Dr William Brace of the University Health Service. Since the examination of 1941 he had led a normal life but had noted mild dyspnea and palpitation on exertion. X-ray examination showed that the tumor had increased to the dimensions of 10 by 8 cm. The blood pressure was 155/100-105. There were no abnormal urinary findings. Three blood Kahn tests were negative, the hemoglobin was 95 per cent and the leukocyte count was 4,050. A provisional diagnosis of aortic coarctation on the basis of extrinsic pressure by a neoplasm (probably a neurofibroma) was made. Thoracotomy was advised and performed on October 20.

The operation¹⁹ was carried out under intratracheal ether vapor anesthesia. Through a posterolateral incision the fifth rib was resected and the sixth rib divided posteriorly. Greatly enlarged blood vessels were encountered during the incision of the extracostal muscles. There were no pleural adhesions. A saccular aneurysm of the upper descending aorta, 11 cm long and 8 cm wide, and having a thin wall was exposed in the costovertebral gutter. Its upper pole was 5 cm inferior to the left subclavian artery and its attachment to the aorta was about 7.5 cm long. A second, or daughter, aneurysm, measuring 2 by 2 cm, arose from the anterosuperior wall of the large aneurysm. A forceful thrill was present in the aneurysm. The pulsations in the aorta above it were strong but

aorta (7.5 cm in length) was removed. The divided ends of the aorta were oversewed with silk, in addition, a pedicled flap of the posterior aneurysm wall was turned over the open end of the superior segment of the divided aorta and tacked to the aortic wall. At the time the aneurysm was removed the blood pressure rose to 250/130 but after closure of the thoracic wall it fell to 150/100.

Pathologic examination by Dr R J Parsons revealed that the narrow margin of normal appearing aorta attached to the specimen showed microscopically more muscular tissue and fewer elastic fibers than would a normal aorta. The wall of the aneurysm consisted of dense hyaline connective tissue. At the margin of the aneurysm where it joined the aorta the media of the aorta showed fraying of the muscle with interdigitation of fibrous connective tissue with its musculoelastic coat. There were atheromatous plaques on the inner surface of the aneurysm.

The feet remained warm throughout the operation and afterward. Immediately after operation the posterior tibial pulses could be felt and the following day the dorsalis pedis pulses were easily palpable. By the tenth postoperative day the brachial blood pressure had risen to 220/130, this pressure was maintained, except for a 15 to 20 point drop in the diastolic pressure, until the patient was discharged from the hospital. The nonprotein nitrogen was 38.5 mg per hundred cubic centimeters on the first postoperative day and remained within normal limits (ranging from 39.2 to 18.1 mg per hundred cubic centimeters). The urinary output was normal. On the fifth

¹⁹ Performed by John Alexander assisted by Francis N. Byron, Carlos A. Peschiera and William Takahashi, anesthesiologist Mrs. Anne M. Collier.

postoperative day the glomerular filtration rate was 124 cc per minute (normal, 125 cc per minute), the effective renal blood flow was 800 cc per minute (normal, 700 cc per minute), and the urea clearance was 125 per cent for the first hour and 90 per cent for the second hour. On the first day after operation the urine contained 2 to 5 white blood cells and 25 coarsely granular casts per high power field, which we attributed to urinary concentration, as there were no albumin or red cells. Subsequent examination showed complete disappearance of the cells and casts by the tenth postoperative day. Examination of the eyegrounds on the eleventh day revealed no localized angiospasm.

The convalescence was uneventful until seventeen days after operation, when acute cardiac decompensation occurred, being evidenced by the rapid onset of dyspnea, mild cyanosis, blood streaked sputum, congestive rales and liver engorgement. The symptoms began to recede rapidly on the third day under treatment by oxygen inhalation, morphine, a 350 cc venesection, rapid digitalization, mercupurin and ammonium chloride. Thereafter, until discharge, on November 26, the clinical course was uneventful except for headaches, of which he had two or three a day. At the time of discharge the blood pressure was 215/105, the urea clearance was 51 per cent and the non-protein nitrogen was 181 mg per hundred cubic centimeters.

On Jan 13, 1944 the patient was readmitted to the hospital for study and was discharged ten days later. Since the time of his first discharge his physical activities had been considerably restricted. On fine days he took a half hour's leisurely walk in the afternoon during which he experienced no dyspnea.

Fig. 2—Before and after resection of the aneurysm. Actually, the aneurysm was 11 cm long; its attachment to the aorta was 7.5 cm long.

or palpitation. The rest of the time he spent in bed except for short periods at mealtimes. He experienced no fatigue and felt that he could have done much more if his activities had not been restricted. Headaches occurred rather frequently and tended to last all day. They consisted of a dull ache over the eyes and were sometimes accompanied by mild nausea. On two occasions he had attacks of pain radiating down the spine from the occiput to the hips with a feeling of stiffness in this region. Both attacks were relieved by heat and massage. Some blurring of vision occurred after reading, both with and without glasses. No symptoms of cardiac decompensation had occurred. The urinary output was apparently normal and there was no nocturia. His feet remained warm, somewhat warmer, he believed, than before operation. He recalled that, prior to operation, localized areas of blushing would occur over the arms and upper part of the thorax. These still occurred but were less pronounced than previously. His weight remained constant.

On examination he appeared to be in good general health. A few small irregular hyperemic areas, which blanched on pressure, were present over the upper anterior part of the chest. The descending branch of the transverse cervical artery was readily palpable, as were the intercostal, the lateral thoracic, the internal mammary and the inferior epigastric arteries. The femoral, popliteal and dorsalis pedis pulses were faintly palpable and the lower extremities were warm. A systolic murmur was audible over most of the thorax, being loudest over the precordium and in the axillae. Murmurs were also heard over the inferior epigastric arteries.

The blood pressure readings at the right arm were 200/118 in the prone position, 190/115 sitting and 198/118 standing. Those of the left arm were 198/114, 200/120 and 205/125 respectively. After he had walked several hundred feet the blood pressure in the sitting position fell to 178/105.

Fig. 3—Appearance of aneurysm and adjacent portions of aorta during operation. The aspirator points at the daughter aneurysm. The lung is seen anteriorly.

Fig. 4—Resected aneurysm (stuffed with gauze). The probe is in the resected portion of the aorta.

dates in the region of the macula. The visual fields were normal. Thoracic x-ray examination revealed no cardiac enlargement or significant alteration in the contour of the heart or great vessels. Apart from elevation and partial fixation

of the left diaphragm no abnormalities were present. The electrocardiogram showed no significant alteration.

Examination of the urine revealed 2 to 5 white blood cells and 5 to 10 red blood cells per high power field. The urine concentration test showed a maximum specific gravity of 1.032 (normal, 1.025 to 1.032). The phenolsulfonphthalein test (intravenous) revealed 30 per cent excretion of the dye in fifteen minutes, 42 per cent in thirty minutes and 82 per cent in one hour. In two hours 87 per cent had been excreted. The urea clearance was 115.5 per cent. The blood nonprotein nitrogen was 25.8 mg per hundred cubic centimeters. The blood hemoglobin was 86 per cent and the leukocyte count 8,050.

A check-up examination, Oct 17-18, 1944, revealed that during the first six months of this year the patient gradually increased his activities and on July 1 he reentered the law school. Since then his curricular and extracurricular activities have been the same as before operation. Now, one year after operation his health is subjectively good. There is no dyspnea.

test (intramuscular) shows 5 per cent excretion of the dye in fifteen minutes, 20 per cent in thirty minutes, 60 per cent in one hour and 90 per cent in an hour and a half.

COMMENT

The pathogenesis of the aneurysm in this case has not been definitely established. The external circumference of the aorta just above the aneurysm was only slightly narrower than normal. However, in the absence of an organized obstructive clot in the aneurysm it is necessary to assume the presence of a coarctation in order to explain the remarkably well developed collateral circulation, the bilateral rib notching and the absence of pulsation of the aneurysm and of the aorta below it.

Hamilton and Abbott,²⁰ in their comprehensive review of the subject, state that coarctation may occur

Fig 3.—A, section through the wall of the aneurysm showing hyalinization of the connective tissue and absence of elastic fibers. Verhoeff stain. B, section through the normal aortic wall below the aneurysm showing the abundance of elastic fibers in the media. Verhoeff stain.

his feet are warm, and exercise causes no claudication of his legs. He can ride a bicycle and play four consecutive games of ping pong without difficulty. His headaches have disappeared and he describes his vision as "perfect."

There is now a palpable systolic blood pressure of 90 mm of mercury in the legs. The blood pressure in the right arm is sitting 190/115, standing 185/115, lying 195/110, lying after exercise 240/130. The corresponding figures for the left arm are 205/115, 195/120, 210/120, 220/120. Comparison of the electrocardiograms with the previous tracings shows no change. Chest x-ray films, compared with the January films, show a definite symmetrical cardiac enlargement and an increase of the notching of the ribs. Dr H. F. Falls of the Department of Ophthalmology reports that the acute process in the retinas is at a standstill; the fundi are better than at the previous examination, no fresh hemorrhages or exudates have occurred; localized angiospasm is still present. The urine examination reveals no abnormality, the specific gravity of the first morning specimen is 1.018. The blood nonprotein nitrogen is 26.3 mg per hundred cubic centimeters. The phenolsulfonphthalein

without external evidence of its presence. In these cases the obstruction is caused by a diaphragm composed of the intimal coat. In our case it was not possible, of course, to examine the aortic lumen for any appreciable distance above or below the aneurysm. The location of the aneurysm not far below the ligamentum arteriosum is significant, since in the great majority of cases the coarctation is at the level of the ligamentum.

Although in the usual case of coarctation at the ligamentum level the aortic dilatation is fusiform involving the ascending aorta just above the aortic valve ring and, to a lesser extent, the aortic arch, it is known that aneurysm may occur just below the point of coarctation and that such an aneurysm may reach saccular proportions occasionally progressing to rup-

20. Hamilton W. F. and Abbott M. E. Coarctation of the Aorta of the Adult Type. *Am Heart J* 3: 381-421 (April); 574-618 (June) 1928.

ture Hamilton and Abbott²⁰ cite 8 cases in which this occurred. These authors state that the aneurysm formation at this site is the "direct result of the return of the collateral circulation [to the aorta below the level of obstruction] through the aortic intercostals."

Fig 6—The patient one month after operation

So great is the influx of blood at this point in such cases that the aorta immediately below the constriction where the upper aortic intercostals are given off is frequently dilated in a bulbous fashion. Zaslow and Krasnoff,²¹ who recently reported a case of rupture of a thoracic aneurysm located just below a constriction, also offer this explanation for the formation of the aneurysm.

The explanation that the scant amount of elastic tissue in the media of the segment of aorta attached to the inferior end of the aneurysm in our case might have been the cause of the dilatation fails to account for the well developed collateral circulation and for the absence of pulsation of the aneurysm. The sac itself contained only fresh blood clot and its wall was composed of dense hyaline connective tissue 2 mm in thickness.

Although the degree of hypertension that is usually present in cases of aortic coarctation was present in our patient, the considerable rise in both systolic and diastolic pressure during and following operation presumably occurred as a direct result of increased resistance created by the aortic ligation. The brief period of cardiac decompensation that began seventeen days after operation and that responded rapidly to treatment was probably due to the greatly increased cardiac load.

The subsequent reduction in blood pressure suggests that the collateral circulation is becoming more efficient.

COLLATERAL CIRCULATION

The collateral circulation in our patient was remarkably good and it sustained circulation after ligation of the thoracic aorta. The improved pulsations in the

lower extremities and the subjective increase in warmth of the feet suggest an actual improvement in circulation after the ligation, but the postoperative rise in blood pressure of the upper extremities and the brief period of cardiac decompensation are stronger evidence that the circulation was impaired by the ligation. Physical examination of the patient readily demonstrates that both the cervical and the subscapular branches of the subclavian arteries and the anastomoses of the internal mammary system are bearing a considerable share of the collateral circulatory burden. It may be assumed that the spinal and esophageal arterial anastomoses are also involved. Figure 7 illustrates the available anastomotic channels.

In the case of complete coarctation reported by Gitlow and Sommer,²² collateral circulation was chiefly by way of the internal mammary, superior intercostal and subscapular arteries. Hamilton and Abbott²⁰ stress the importance of the internal mammary and lateral thoracic channels. Bramwell and Jones²³ had the opportunity of studying the collateral circulation in a case of complete aortic coarctation just distal to the left subclavian. They injected the arterial system with barium paste and obtained roentgenograms which excellently outlined the anastomotic channels. In their case the main anastomoses were (a) by way of the musculophrenic branches of the internal mammary to the

Fig 7—Schema of collateral circulation in cases of occlusion of the thoracic aorta just inferior to the left subclavian artery. Oblique projection after Bramwell and Jones²³

inferior phrenic branches of the abdominal aorta and to the smaller superior phrenic branches of the thoracic aorta, forming a network above and below the

diaphragm, (b) by the scapular and cervical branches of the subclavian and axillary arteries to the lateral and dorsal branches of the aortic intercostals, forming a network about the scapula and in the neck, and (c) by way of the superior intercostals through the upper two intercostals to the next lower intercostals. Their case, in contrast with ours, demonstrated little collateral circulation through the superior and inferior epigastric arteries.

In their experimental work on aortic ligation Owings and Hewitt²⁴ showed, by the injection-roentgenogram technic that the greater part of the blood in their surviving dogs passed through the internal mammary and phrenic arteries into the intercostals below the site of ligation and then back into the aorta and also through the inferior epigastrics into the iliac arteries.

EFFECTS OF AORTIC LIGATION ON RENAL FUNCTION AND BLOOD PRESSURE

Our patient affords an unusual opportunity to study the effects of aortic ligation on renal function. The only other patient whose thoracic or abdominal aorta was completely ligated above the level of the renal arteries and who lived longer than three days was Reid's⁹ patient, who lived for one and a half months after complete ligation of the abdominal aorta above the celiac axis. No renal function studies were reported for the case. The only other studies of renal function in the presence of partial or complete occlusion of the aorta above the renal arteries that are known to us have been made in experimental animals and in human cases of aortic coarctation which may or may not have produced complete obstruction. Although a number of investigators, notably Halsted,²⁵ Pearse,²⁶ Reid,²⁷ and Matas and Allen,²⁸ have completely occluded the aorta proximal to the renal arteries in dogs, only the protocols of Owings and Hewitt²⁴ are sufficiently complete to show the late effects on blood pressure and renal function. They practiced a method of gradual aortic occlusion extending over a period of several months and finally were able to perform complete section of the thoracic aorta. One of these dogs survived for three years and six months before being killed. During this time the blood pressure remained consistently elevated, ranging from 182 to 190 systolic in the carotid and from 142 to 157 systolic in the femoral. The phenol-sulfonphthalein test varied from 45 to 65 per cent (total after one hour) and nonprotein nitrogen from 29 to 64 mg per hundred cubic centimeters. Two years and four months after aortic division retinal separation occurred. In another dog killed five months after division of the thoracic aorta the blood pressure varied from 207 to 220 systolic in the carotid and from 100 to 140 systolic in the femoral. After five months, although the vision seemed normal, the eyegrounds showed hemorrhage and exudates.

The effects of sudden aortic constriction above the renal arteries have long been recognized. Guinard⁵

in 1909, as a result of clinical observation in his case of ligation of the thoracic aorta, stated that "ligation of the aorta in the thorax permits sufficient collateral circulation through intercostal anastomoses to nourish the inferior members, but the physiological functions of the kidneys require a notable arterial pressure in the renal arteries." Goldblatt and Kahn²⁹ and Goldblatt, Kahn and Hanzal³⁰ demonstrated that constriction of the aorta just above the renal arteries resulted in hypertension, both above and below the constriction, after twenty-four hours. Ryland³¹ found that partial occlusion of the aorta above the renal arteries of rats produced hypertension, whereas partial ligation just below the renal arteries did not produce hypertension.

Even in human cases of long standing aortic constriction with an apparently adequate collateral circulation the hypertension is interpreted in the light of primary reduced renal blood flow by Friedman, Selzer and Rosenblum,³² who measured the effective renal blood flow and the rate of glomerular filtration by means of the diodrast and inulin clearance tests in a group of 11 normal human subjects and in a group of 6 patients with coarctation of the aorta. Their studies indicate an appreciable decrease in the renal blood flow in the coarctation patients as compared with the normal controls. The glomerular filtration rate, however was normal, they interpret this finding as indicative of secondary glomerular efferent arteriolar spasm.

The consistently normal kidney function tests in our patient, together with the lack of retinal angiospasm during the early postoperative period, led us to hope that the hypertension was largely on the basis of increased resistance created by the aortic ligation and that, as the collateral circulation improved, the hypertension would decrease. The subsequent development, however, of arteriolar angiospasm seems to imply a graver prognosis.

PRINCIPLES OF OPERATIVE TECHNIC OF AORTIC LIGATION

With regard to the operative technic, we feel that the choice of ligating material is of considerable importance and that the chance of necrosis and rupture of the aorta at the site of the uppermost ligature was reduced by our having used a ligature of broad cotton tape. In 6 of the 9 patients who survived ligation of the abdominal aorta for a sufficient length of time to test the efficacy of the ligating material, cotton tape was used. In no case in which cotton tape was used was death due to the cutting of the ligature. Halsted³³ in his early aortic ligations, both clinical and experimental, used broad aluminum bands, but these consistently cut through the aortic wall, in 1 case rupture at the site of ligation occurring forty-seven days postoperatively. Fascia lata as a ligating material has been found both unreliable and dangerous by Halsted²⁵ and by Pearse,³⁴

who found that considerable relaxation of the ligature occurred and that the fascia absorbed in from three to four months without stimulating adequate scar tissue formation. As pointed out by Reid,³⁵ the width of the ligating material should increase in direct proportion to the size of the vessel. Pearse³⁶ in a more recent paper describes his experiments with cellophane ligatures, this material seems to hold considerable promise in the ligation of large arteries, since it causes violent tissue reaction with the subsequent formation of dense scar and gradual occlusion of the vessel.

The placing of the uppermost ligature just inferior to the left subclavian artery in our patient eliminated a blind pouch and tended to shunt the blood stream directly into the subclavian. We resected the aneurysm, together with a 75 cm length of the aorta, rather than merely ligating the aorta above and below the aneurysm, because it is known that an artery ligated in continuity tends to become recanalized, and because rupture at the site of ligation in continuity is more likely to occur. The thinness of the wall of the aneurysm and the enlargement of the sac during the twenty-two month period of observation were strong evidence that rupture would occur within a few months or, possibly, a few years, if the blood pressure within the sac continued

TREATMENT OF ANEURYSM OF THE AORTA

The treatment of aortic aneurysm is notoriously ineffective, chiefly because the walls of aneurysms are composed of degenerated tissues. Treatment of the syphilis that is the etiologic agent in a majority of cases is the standard practice but rarely prevents a fatal outcome. Various methods of surgical treatment have already been mentioned in this article. The only thoracic aortic aneurysm successfully treated by surgical means is that of our patient. Among the 8 cases of "successful" ligation of the abdominal aorta mentioned in the first part of this article, the lesion was an aneurysm of the abdominal aorta in 5, of the right common iliac artery in 1, of the terminal aorta and both common iliacs in 1 and a malignant neoplasm in the pelvis with transmitted pulsation in 1 (Hamann¹⁰). Success with regard to control of the aneurysm was attained in the cases of Matas,¹¹ Brooks,¹² LaRoque,¹⁶ Bigger¹³ and at least partial success in Elkin's¹⁷ case.

Surgical measures that have not proved successful in the control of aneurysm include ligation of one common carotid and one subclavian artery (for aneurysm of the aortic arch), the wrapping of an aneurysm with fascia lata grafts or aluminum bands, plication of the wall of an aneurysm, periarterial sympathectomy, injection of gelatinous material into an aneurysm and the scratching of the wall of an aneurysm with a needle. The decompression of large aneurysms which are pressing against the thoracic wall by the resection of ribs, cartilages or the sternum has occasionally given great temporary relief of distressing symptoms.

By far the most encouraging work that has ever been done in connection with the treatment of aneurysm of the thoracic or abdominal aorta is, in our opinion, that of Blakemore and King³⁷ relating to wiring and elec-

trothermic coagulation. In the past the results of wiring have been uncertain and relatively unsatisfactory, although brilliant in occasional cases. By an original and somewhat complicated technic, Blakemore and King produce complete mass clotting of the blood within an aneurysm by the passage of an electric current through a great length (average, 118 feet) of very fine insulated wire that has been introduced into the aneurysm through a special needle. The great length of wire slows the velocity of the blood within the aneurysm. Measurement of the rate of cooling of a given segment of wire with a given electric current determines the velocity of the blood and therefore the amount of wire and of current needed to produce coagulation. This control is sufficiently accurate to permit the complete coagulation of the blood within a saccular aneurysm having a mouth of smaller diameter than the diameter of the aneurysm itself but not of the more rapidly moving blood within the aortic lumen proper. In saccular aneurysms having a larger mouth and in fusiform aneurysms sufficient coagulation can be produced in the high velocity blood flow to relieve the strain on the sac wall by strengthening the wall. Twenty-six patients with syphilitic aneurysm of the aorta were treated before Jan 1, 1940. Nine of these patients are living with inactive aneurysms an average of seven years after treatment. Seventeen of the 26 patients died from a few hours to eight years after wiring, some of them having had great symptomatic relief.

With regard to our patient we fully realize that his return to health is far from assured since the last check-up examinations were made only three months after the operation and since he has considerable hypertension and retinal angiospasm, exudates and hemorrhages. We particularly wish to emphasize that the early success in our case has no bearing on the management of aneurysm in general. In syphilitic aneurysms the aorta itself is degenerated and collateral circulation is usually not well developed. In typical cases of aortic coarctation the aortic dilatation is fusiform and involves the ascending aorta. Our patient is unique in that all the factors essential to the success of the operation we performed were present: his youth and good general health, the absence of syphilitic disease of the aorta, the presence of a well established collateral circulation and the location of the aneurysm, which permitted the placing of the proximal ligature on the aorta below the left subclavian artery.

SUMMARY

- 1 In our case an aneurysm of the thoracic aorta, together with a part of the aorta, was successfully resected for the first time.
- 2 Follow-up data relating to the circulation and renal function, among other things, were obtained three months after operation.
- 3 The aneurysm probably arose in connection with an aortic coarctation, the presence of which is presumed because of hypertension, a well developed collateral circulation, notching of ribs and weak arterial pulsations in the lower extremities.
- 4 The operation used in our patient has no bearing on the management of aortic aneurysm in general because in him there was an exceptional combination of circumstances that made the operation feasible.

GROWTH ARREST FOR EQUALIZING LEG LENGTHS

J WARREN WHITE, M D
AND
SAM G STUBBINS JR, M D
GREENVILLE, S C

Our purpose in this paper is to popularize a simple surgical procedure which we have found to be of great value in solving the problem when in children one leg is enough shorter than the other to produce immediate or probable future disability. Since Phemister's¹ important article reporting the original conception was published eleven years ago and as other articles discussing the complicated bone growth problem and still others reporting uncertain end results from his operation have appeared, it is felt that a discussion of the procedure would be justified after doing over two hundred and fifty epiphysiodiaphysal fusions in which few difficulties or complications have been encountered.

We wish to call attention to three important points which we feel should be emphasized in order to dispel some of the apprehension existing relative to the performance of this so-called ir retrievable operation.

First of all we will describe briefly a surgical technic which we have felt to be reliable as an alternative procedure to the one originally described by Phemister¹ over eleven years ago, which former in our hands at least is more easily accomplished and has resulted to

Fig 1—One half inch square mortising chisel with obturator

date in the development of no deformities attributable to the operation.

Second, we would emphasize the necessity of a suitable method of recording leg length discrepancies more accurately than the conventional tape line measurement from the anterior superior spine to the internal malleolus.

Third, we suggest a simple method of calculation sufficiently accurate, in the face of so many variable factors associated with bone growth, to make it of practical use.

It is not within the province of this short paper to discuss the merits of the various methods employed to solve this leg length discrepancy problem, but femoral shortenings will be mentioned as adjuncts to Phemister's¹ epiphysiodiaphysal fusions or growth arrests, as we prefer to call them. A preliminary report on a growth arrest technic after using it for four years was published by one of us six years ago, in which work Dr W P Warner Jr collaborated.² As the same technic has continued to prove satisfactory after six more years' trial a ten year report was felt justified, particularly as few end result accounts have appeared in the literature and as several papers have been published which in our estimation have tended to con-

fuse the subject and to detract from the value of the operation.

The fact that one of us after having performed over ninety femoral shortenings before has done only two in the last two years, and those in adults, shows how that procedure has been outmoded and accentuates the utility of this relatively simple growth arrest operation in

Fig 2—Curve showing growth rate at various ages. Figures above curve represent ages; figures below curve indicate growth in inches between ages shown above. Metropolitan Life Insurance actuarial figures.

correcting leg length discrepancies in children before growth maturity has been attained.

The deformities that have developed following a growth arrest operation we believe can be laid directly to an inadequate treatment of the actively growing zone of metamorphosing cartilage on the diaphysal side of the epiphysal cartilaginous plate. Our personal feeling is that the technic originally devised by Phemister may not include sufficient depth of bone, particularly on the epiphysal side of the graft, where one tends to include too little bone for the establishment of an adequate "beach head" across the layer of cartilage, to use a timely military term. For the success of this operation solid bony union must develop between the epiphysis and the diaphysis at the site of the surgical attacks, and therefore we feel that the more extensive the bone surface opposed, the more certain is bony union. A real nonunion at this point explains the development of most of these distressing deformities.

Fig 3—Tracing of anteroposterior and lateral x-ray films to show direction approximate depth and relative size of square plugs of cancellous bone (including small portion of metaphysal plate) removed with the square mortising chisel and reintroduced with the obturator (fig 1) rotating it 90 degrees to interrupt the continuity of the plate. Curretting of the adjacent portion of the plate not shown.

Unfortunately Phemister in his original article does not mention the depth of his epiphysiodiaphysal graft which we feel to be so important. He does, however, advocate the chiseling out of the epiphysal plate to a depth of 1 centimeter anterior and posterior to the

² White J W and Warner W P Jr. Experiences with Metaphysal Growth Arrest. *South M J* 31 411-414 (April) 1933.

time, and we feel that it is accurate enough to be depended on in the face of so many other variables.

Regardless of the age and size of the child, we have figured that a growth arrest procedure at the distal femoral epiphysis would retard growth at the rate of $\frac{3}{8}$ inch a year, while at the proximal end of the tibia and fibula it is retarded $\frac{1}{4}$ inch. This figuring appears absurdly simple, but its use has not led us astray in our series dating back at least ten years, and we feel justified in recommending it for practical use. These figures were published in the preliminary report.² We figure that growth ceases in boys at 17 and in girls one year earlier.

This operation should be performed largely on those in whom at the age of 10 or 12 there exists upward of 2 inches shortening, usually a result either of an early attack of poliomyelitis or of some destruction of an epiphyseal plate which will, if nothing is done, go on to the development of a serious discrepancy, producing, in addition to other handicaps, further disability. If, for instance, at the age of 12 there exists 2 inches shortening following an attack of poliomyelitis eight years before, and growth arrests are done above and below the knee, approximate equalization can be expected in leg length at maturity, i. e. at about 16

Fig 7—Congenital deformity of right leg including flexion of knee and absent tibia

Our series of 149 Shrine Hospital cases arrested before January 1943 comprises 202 separate growth arrests, the arresting of both bones below the knee being called 1 arrest procedure. Twenty-seven more cases or 37 more arrests have been done since that time, indicating that almost half the cases were arrested above and below the knee, only 16 of which were done at the same time. It is significant that, as we gained experience, more double (i. e. above and below the knee) arrests were done. In the last year and a half we have done half as many again, i. e. 8.

In the cases done before 1943 the shortening was caused by poliomyelitis in 85, or 57 per cent, while osteomyelitis destroyed the growth function of an epiphyseal plate and resulted in shortening in 11.5 per cent. These were the cases in which an annual increment had to be figured in, which was not so definitely a factor in many of the other cases. There were 19, or almost 13 per cent, hip problems in which extra accuracy had to be employed because of the impossibility of pelvis tilting compensation.

In 18, or 12 per cent, of the entire series femoral shortenings were employed, but most of these being done early in the game in all 4 of them for instance in 1934, when this series started. Only 1 has been done since 1939, during which year 2 were performed.

In conclusion, therefore, we feel justified in recommending this simple surgical procedure and have sug-

gested first a technic which in our hands has been relatively free of complications, second, a practical plan of recording leg length discrepancies and, third, a simple almost empirical scheme of calculation of sufficiently proved accuracy in a large number of cases to be relied on.

We have found that the following through to maturity of these problems has been of absorbing interest and hope that this paper will stimulate surgeons to perform this most valuable operation more frequently. The watching of these long legs grow shorter as the years go by has added immeasurably to the interest of our follow-up clinics.

206 East North Street

ABSTRACT OF DISCUSSION

DR S L HAAS, San Francisco Drs White and Stubbins have presented an ingenious method for arresting epiphyseal growth. I have been performing a more complicated operation, either removing the entire epiphyseal plate or at least destroying the complete circumference. This was necessary because in some of the earlier cases in which a part of the plate remained we got a genu valgum or varum. I should like to ask Dr White if he gets any deformities. Epiphyseal arrest has its limitations, as it can be done only during a certain period of growth. It is also necessary to anticipate the amount of subsequent growth which in spite of the tables of Hatcher and those of Abbot and Gill are only an average. Dr White's method of anticipating growth is simple and seems to be fairly accurate on the average patient. The alternative method, as brought out in the paper, is to shorten the good leg. This is more accurate and if done late in the growing period one can remove the desired amount of bone to equalize the length discrepancy. The objection to both epiphyseal arrest and bone shortening operations is the necessity of subjecting the usual good leg to the risk of operation. Sufficient time has elapsed to show that complications following such operation under good conditions and by competent surgeons are few. We performed lengthening operations almost exclusively up to four or five years ago. On checking our operations at the Shriners Hospital in San Francisco my associates and I found we were performing about ten lengthening operations a year previously, while now we do about one a year. Lengthening operations have a greater hazard. It is because of special indications such as when there is a great inequality in length and a shortening operation would present a grotesque stature, also when the patient or the parents refuse to have an operation performed on the good leg.

DR C HOWARD HATCHER, Chicago We are seeking not mathematical accuracy in leg equalization but an approximation which will improve the gait when the effect of the operation has been obtained. There is only one definite thing about growth from the lower extremities, which is the percentage of growth at the various epiphyses. That does not vary with individuals nor does it change at any time during the period of growth from that epiphysis except in dyschondroplasia. Dr White estimates that girls continue to grow from the lower extremities until they are 16 or 17 years old. That has not been my impression nor is it indicated by studies such as those of Lowry and Flores. Girls do not mature as regularly as boys do, and they mature earlier. In general, epiphyseal arrests have no value in the female if menstruation has started, because after that time the girl will grow no longer from the lower extremities, she will increase slightly in height from growth of the spine. The records of lengths by long x-ray films, which are extremely expensive and time consuming are useful in evaluating a series of cases. However, clinical methods are perfectly adequate for ordinary use. The type of operation done does not make much difference. If the periphery of the epiphysis is stripped, growth arrest will usually result. It can be assured by producing a firm bony bridge. It is unnecessary to attempt to destroy the central portions of the cartilage. Disease or injury of the central portions of the cartilage may not interfere with growth at all. To destroy the central portion at operation weakens the bone and predisposes to fracture. I prefer to get

a good wide portion of the peripheral bone, not deeper than 5 to 10 mm, and see that there is firm bony contact. In this way there is no danger of fracture, so I have not hesitated to let patients up in from seven to ten days and to permit them normal activity. The closure of the epiphysis can be checked by roentgenograms three to six months postoperatively. If there is any failure of arrest on one side, a second operation will prevent the development of deformity, which I have had in 1 case. In an injury of the epiphysis in which shortening has already occurred on one side the opposite epiphysis may be closed and the operation combined with metaphysal shortening to secure an immediate and permanent result. The use of the operation in prevention of deformities is one of its most important applications. When fracture or disease has produced unequal growth arrest of the epiphysis, early epiphysal arrest on the side opposite to the injury may prevent deformity and irreparable damage to the joint.

DR J WARREN WHITE, Greenville, S C. As regards Dr Haas's inquiry about deformities, we have not had any that were bad enough to require operation. There was one deformity that developed following the packing of my square hole with bone chips rather than putting in a solid piece of bone, but that happened so near the end of the growth period that correction was not necessary. The next one was in a case of congenital deformities (arthrogryposis) in which I do not know whether my operation produced the bowleg or whether it was happening anyhow, since it happened on the severely deformed other side as well, so I am not taking all the blame for that. By and large we have not had any deformities owing largely, I am confident, to the large exposure of bone on either side of the metaphysal plate, insuring the solid bony union that Dr Hatcher referred to. I think that I am in error (and I appreciate Dr Hatcher's bringing it to my attention) relative to bone maturation age and shall correct my calculations accordingly, calling it one year earlier. In girls the point of the beginning of the menses as regards bone age is an important one to bear in mind. However, in spite of not making use of that, these figures of mine have allowed me to come out correctly in applying my simple arithmetical calculations to the various problems. I do not think we need to fear the development of deformities if we do an adequate operation. If we are not sure of the adequacy of our operation of course we should not do it.

(3.2 mg of 2 methyl-1, 4-naphthohydroquinone-3-sodium sulfonate) was administered subcutaneously in the outer aspect of the right thigh.

The infant was given subcutaneous injections of dextrose and saline solution in the scapular regions and progressed satisfactorily for the next two days. On the second day of life another cubic centimeter of "Hykinone" was administered by means of a 25 gage hypodermic needle into the lateral aspect

Sloughing of toes leaving heads of the metatarsals exposed

of the left thigh. Approximately twelve hours later the nurse reported an unusual bluish white discoloration of the left lower extremity from the junction of the middle and lower thirds of the thigh to the toes. When a medical officer viewed the extremity a few minutes later this area was completely blanched except for the toes, which showed intense purplish discoloration and two purpuric areas, each about 1 inch in diameter, on the anterior tibial surface. The infant made no attempt to move this extremity. In view of the findings, a diagnosis of left femoral thrombophlebitis with concomitant vasospasm was made, with no attempt to specify a definite cause for this vascular disturbance. Although "Hykinone" was the only material injected into the extremity there was no positive evidence to indicate that it was a factor in this instance.

In view of the weight and poor general condition of the infant, therapy was debatable. However, since it was felt that death would ensue if no relief of the vasospasm was obtained, it was decided to attempt a lumbar sympathetic block. This was done approximately six hours after the onset. Blocking of the left lumbar sympathetic segments being accomplished by injecting a total of about 10 cc of 1 per cent procaine hydrochloride in the appropriate left paravertebral areas with a 25 gage hypodermic needle.

Approximately three to four minutes after the completion of the injections the left leg became warm and pink except for the previously described purpuric areas. The pink color soon faded to a cyanotic color indicative of venous obstruction. It was then decided to repeat the lumbar sympathetic block as frequently as the appearance of the extremity warranted. Seven hours after the first injection the extremity was again blanched sufficiently to justify repetition of the procedure, with the same gratifying results. The color of the extremity remained good until the following day (about thirty-four hours after the onset) when blanching was again prominent and left lumbar sympathetic block was again repeated. The color again became pink and gradually faded into a cyanotic hue. During the acute

Clinical Notes, Suggestions and New Instruments

LUMBAR SYMPATHETIC BLOCK IN A PREMATURE INFANT

CAPTAIN ROBERT D. DICKINS
Chief of Surgical Service, Station Hospital AAF Pilot School
Advanced Two Engine, Altus Army Air Field, Altus, Okla.

AND

CAPTAIN JULIUS B. RICHMOND
MEDICAL CORPS, ARMY OF THE UNITED STATES

In view of the recent advances in the treatment of peripheral vascular disorders, we believe it is of value to record our observations of effective lumbar sympathetic block in a premature infant.

After a gestation of approximately seven months a 21 year old white woman delivered a premature infant weighing 3 pounds 2 ounces (1,418 Gm). There had been no antepartum care, the mother had not been seen by a physician until thirty minutes prior to admission to the hospital. It was believed that a mild attack of influenza had brought about premature labor, particularly because of rather severe paroxysms of coughing associated with the illness.

Considerable difficulty was encountered in initiating respiration in the infant. However, after the subcutaneous administration of 0.5 cc of nikethamide and continuous oxygen administration, respiration was established approximately ten minutes after birth. The color soon became good and the infant was placed in a heated crib. An ampule (1 cc) of Hykinone Abbott

illness the general condition of the infant was precarious, the rectal temperature ranged between 99 and 102 F. Because of the ever present hazard of hemorrhage in the premature, no anticoagulants were administered. No laboratory studies were attempted. Glucose in saline solution was given subcutaneously regularly to maintain the hydration and nutrition of the infant. Small quantities of breast milk were taken by mouth.

The left leg maintained good color except for the toes, which continued to be discolored. One week after the onset it seemed obvious that the toes were gangrenous and would slough. No intervention was undertaken and on Jan 28, 1944, one month after the onset, all the toes sloughed, leaving the heads of the metatarsals exposed, as shown in the illustration. The infant's general condition improved considerably during this time, feedings were well taken and the weight was 4½ pounds (2,041 Gm).

Because of retraction of the soft tissue with resultant lack of nutrition to the metatarsals, disarticulation of all the left metatarsals was effected on February 28, two months after the onset. The wound promptly healed and the infant was discharged from the hospital on March 7, 1944 weighing 6 pounds 13 ounces (3,096 Gm). The infant moved the left lower extremity freely, although the musculature seemed slightly atrophic as contrasted to that of the right lower extremity. The superficial veins of the left lower extremity were more prominent than those of the right.

SUMMARY

- 1 Left femoral thrombophlebitis in a 3 pound 2 ounce premature infant was observed. The etiology is in doubt.
- 2 Treatment by lumbar sympathetic block was effective except for the toes, where the vascular changes apparently had become irreversible by the time the block was performed.

HUMAN ORNITHOSIS TREATED WITH PENICILLIN

F. E. TURGA SEN, M.D., MANITOWOC, WIS.

Human ornithosis is probably more prevalent than is commonly recognized and may be present in a fairly high percentage of the recently increasing number of cases diagnosed as virus pneumonia. The literature on the subject has been recently summarized by Heilman and Herrell.¹ The chief difficulty in establishing the diagnosis is the lack of convenient laboratory facilities in America for making complement fixation tests on the patient's blood serum. As far as I could ascertain, the

features resembles the onset of typhoid except that diarrhea is not present and an atypical pneumonia with a dry, irritating, unproductive cough soon becomes a prominent feature. The mortality rate, particularly in the older age groups, has been consistently high. Therapy with the various sulfonamides has been largely without effect. As reported by Heilman and Herrell,¹ penicillin was definitely curative in a series of experimentally produced ornithosis infections in mice. Penicillin was used in the treatment of the patient who was the subject of the present report with favorable results.

REPORT OF CASE

History.—W. V., a man aged 43, has been a pigeon fancier and has had a loft of homing pigeons in his back yard for a number of years. During the past few months, several of the pigeons have died after a short illness with cough, wheezing, ruffled feathers and in some cases diarrhea. He had been caring for the pigeons himself and had used no precautions in handling the dead or ill birds. Seven days before the onset of his illness he cleaned the loft and inhaled a considerable amount of the stirred up dust. He felt well until Aug 18, 1944, when he became ill with generalized aching, headache and fever. There soon followed a considerable degree of abdominal discomfort with indigestion and gaseous distention, but diarrhea was not present. The temperature became elevated rapidly and the pulse rate was disproportionately slow. He was rather forcibly persuaded to go to the hospital where he might have adequate care and was admitted on August 23.

Physical and Laboratory Findings.—The significant physical findings were a considerable degree of irritability and a slight impairment of mental coordination and judgment attributed to the fever and severe illness. There was a slight degree of photophobia, an atypical consolidation of the left lower lobe posteriorly with the absence of rales, a rather soft enlargement of the spleen so that it was definitely palpable beneath the costal margin on deep inspiration, and rather uniform moderate gaseous distention of the abdomen. The laboratory examination revealed urine normal, red blood cell count 4,260,000 and white blood cell count 9,200 on the day of admission and 11,100 two days later. The differential count was neutrophils 78 per cent, lymphocytes 8 per cent, monocytes 9 per cent, eosinophils 4 per cent and 1 unidentified mononuclear cell. Blood culture was sterile and agglutination tests for typhoid, paratyphoid, undulant fever and tularemia were all negative. A telegraphic report from Dr. K. F. Meyer stated that the patient's serum which was obtained on the fifth day of his illness, fixed psittacosis antigen in a dilution of 1:256.

Four pigeons were taken from the patient's pigeon loft and sent to the Mayo Clinic laboratories, where they were examined by Dr. F. R. Heilman. Of the 4 pigeons examined, 2 were found to have enlarged spleens. From 1 of the pigeons with the enlarged spleen the virus of ornithosis was recovered and identified.

X-ray examination on admission to the hospital revealed a pneumonic type of infiltration centrally in the left lower lung. Subsequent films revealed no spread of the process and by September 15 almost complete resolution had taken place.

Treatment.—As soon as blood samples had been taken (five days after the onset of illness) penicillin was started and was given throughout for a period of seven and one half days by the intramuscular route in divided doses using a solution in isotonic solution of sodium chloride, 10,000 units to the cubic centimeter and a daily amount of 100,000 units being given. No other medication was administered throughout the illness except ammonium chloride, which was given in expectorant doses on the fourth and fifth hospital days for the purpose of obtaining sputum for examination. The penicillin was stopped when the temperature had been normal for three days.

Clinical Course.—The patient's general condition fairly well paralleled the temperature chart and he was discharged from the hospital on September 2 to his home where he convalesced. He returned to light work in two weeks and was apparently fully recovered one month after the onset of his illness.

Ornithosis—Penicillin therapy

laboratory of Dr. K. F. Meyer at the University of California is the only one on this continent that does this work.

Ornithosis and psittacosis are strikingly similar in their clinical manifestations and probably differ only in the source and causative virus. The onset is rather gradual and in many

Assistance and advice in the management of this case were given by Dr. Herrell. Laboratory aid was extended by Dr. A. F. Meyer of the University of California and Dr. F. R. Heilman of the Mayo Clinic.
1. Heilman, F. R. and Herrell, W. E. Penicillin in the Treatment of Experimental Ornithosis. Proc. Staff Meet., Mayo Clin. 19: 57-65 (Feb. 9) 1944.

CONCLUSION

This case is reported as an example in which penicillin appeared to influence favorably the course of illness in a case of ornithosis in which the diagnosis was confirmed by complement fixation tests on the blood performed by Dr Meyer. The probability of the disease having been contracted from the pigeons seems further likely because of the identification of the virus by Dr Heilman in pigeons obtained from the loft and examined in his laboratory at the Mayo Clinic. This case is also reported to point out the fact that the disease may occur in this area and probably is more prevalent than is recognized. The chief difficulty in establishing the diagnosis is the lack of convenient laboratory facilities.

926 South Eighth Street

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports HOWARD A. CARTER Secretary

RADIOEAR, MODEL 45-CM, ACCEPTABLE

Manufacturer E. A. Myers & Sons, 306 Beverly Road, Mount Lebanon, Pittsburgh 16

Model 45 CM Radioear with crystal receiver is a three vacuum tube instrument consisting of a transmitter, a special crystal receiver and a battery unit. A midget magnetic receiver may also be used with this instrument. It was not tested with the magnetic receiver, however.

Model 45 CM Radioear

Dimensions — Transmitter 4 inches by 2 inches by $\frac{3}{4}$ inch. Receiver crystal, $\frac{3}{4}$ inch in diameter. Transmitter, receiver and cords weigh 5 ounces. Batteries weigh $12\frac{1}{2}$ ounces.

Batteries — Voltages and current drains are as follows: A battery, 15 volts, current drain at full volume, 60 milliamperes.

B battery, 33 volts, current drain at full volume, 0.22 milli-ampere.

Acoustical Gain — Observations were made by trained observers using fitted ear molds in a tone field, within a sound proof room, seated 5 feet from a loud speaker delivering frequencies of pure sine wave characteristics. The readings are in decibel gain.

Volume Control	Position of Tone	Frequency							
Set at	Control	256	512	1,024	1,448	2,048	2,896	4,096	5,792
$\frac{1}{4}$	Center	9	9	6	11	15	7	5	0
$\frac{3}{4}$	Center	10	10	16	18	22	8	8	1
Full	Center	11	13	19	18	21	2	10	3

Overall gain for speech 45 decibels

Physical and Mechanical Features — The instrument consists of a black plastic case of pleasing appearance. The front surface design is indented. The on and off switch, which is also the volume control, is a knurled disk placed at the top of the transmitter. A tone control at the upper right hand corner gives three distinct frequency emphases. The aid is divided into discrete sections, each of which can be replaced by a service part when servicing is needed. This can be done at the dealer's office without using a soldering iron to make the connections.

Performance — The instrument operates in a very satisfactory manner. However, in the descriptive material it was represented as having a frequency range of 250 to 6,000 cycles. This may be true, but at this high frequency no significant gain is apparent by the method of testing employed by the Council. The three position tone control operated entirely as represented. There is an absolute minimum of case noise, little if any distortion at maximum intensity. Cord noise and feedback squeal are negligible.

Recommendations — The Council on Physical Medicine voted to accept the Radioear, Model 45 CM, for inclusion in its list of accepted devices.

KREISELMAN RESUSCITATOR, MODEL 74-B, ACCEPTABLE

Manufacturer The Ohio Chemical & Mfg Co. Heidbrink Division Cleveland

Model 74-B apparatus consists of three separate independent elements arranged for convenient portability in a carrying case of size sufficient to contain two D cylinders of oxygen, and with provision by means of holes in the bottom of the case for the use of large E cylinders. It is used for administration of artificial respiration.

The elements constituting the outfit aside from the carrying case, are described as follows:

Resuscitator — This consists of the Kreiselman Bellows type Resuscitator, Model 110, recently accepted by the Council (THE JOURNAL, Sept 9 1944).

Oxygen Inhalation Facilities — Inhalation of oxygen by the breathing patient is provided through an automatic adjustable reducing valve to which is attached the manifold having two yokes for the attachment of two oxygen cylinders. The contents of either or both tanks pass through the reducing valve, which is regulated by a handwheel screw. The gas is delivered to two mask-bag assemblies which are attached to a manifold. A 3,000 pound Bourdon type gage is in direct communication with the gases in the tanks and indicates contents at all times.

A gage in direct communication with the low pressure chamber of the automatic reducing valve indicated the amount of oxygen delivered in liters per minute to the attached masks whether one mask is attached or two.

When a mask is detached through removal of the bayonet plug-in of the quick disconnect valve the valve automatically shuts off the flow of oxygen at that point. The automatic reducing valve delivers ample oxygen for breathing purposes for 2 patients.

Aspirator — This apparatus is simple, consisting of a catch jar for fluids, an aspirator connected by flexible rubber tubing and an attached tubing leading to a rubber bulb which is squeezed and released to create vacuum for aspiration.

Accessories — Two sizes of face masks for use with the bellows resuscitator and two sizes of the open type wire airways are supplied. A substantial wrench for opening cylinders is included.

Gas cylinders are held firmly in place by a removable bracket.

The carrying case is of three ply construction covered with a heavy grade of hard fiber. All edges of the case around openings are metal bound and riveted. Substantial draw bolts hold the case cover on firmly. An end handle and a top handle are provided on the case.

Separate compartments in the case provide easy access to masks and aspirator.

Council Investigation — This apparatus was investigated in a clinic acceptable to the Council on Physical Medicine.

The aspirator consists of a large bulb of heavy rubber attached to a small glass jar on the bulb. A rubber tube and metal tip to enter the mouth and throat is attached to this bottle. The Kreiselman inflator performs safe and adequate inflation. Two metal artificial pharyngeal airways are provided. The operator must assure himself that the airway to the lungs is open when using the inflator.

The mask to which oxygen is delivered for inhalation is safe since, if no oxygen flows, the patient can breathe air normally.

Hence, without an oxygen supply and without electric current, this apparatus still permits adequate suction and adequate inflation of the lungs. Also oxygen can be administered to a patient while he is breathing normally.

The Council on Physical Medicine voted to accept the Kreiselman Resuscitator, Model 74-B, for inclusion in its list of accepted devices with the same limitation on the Bellow Resuscitator mentioned in THE JOURNAL, Sept 9, 1944.

PRIMARY ATYPICAL PNEUMONIA

In the past decade, outbreaks of acute pneumonitis have been described in civilian populations,¹ schools and more recently in U S Army camps - which have differed from the lobar and lobular (bacterial) pneumonias in their clinical course, signs, symptoms, x-ray appearances and laboratory findings, these have been designated therefore as "atypical pneumonia" or "primary atypical pneumonia, etiology undetermined." As a rule the clinical onset of the disease is gradual, with constitutional symptoms, fever and a dry, nonproductive cough and with minimal physical signs in the chest. The changes in the chest contrast significantly with the well developed spotty lesions that can be demonstrated by x-ray films of the lungs. In short the clinical aspects of the disease are not unlike those of a severe upper respiratory infection.

The etiology of atypical pneumonia is still obscure. Weir and Horsfall² isolated from a human case a virus pathogenic for the mongoose, while Eaton and his associates³ obtained a virus that was pathogenic for the cotton rat, the hamster and the chick embryo. The first investigation was made on the Central Eastern seaboard and the second in the Far West. Up to now others have not confirmed these results, but the attempts have been made usually in other geographic areas.

Of great interest is the recent report of Golden⁴ on the pathologic aspects of the disease. From the examination of many cases Golden found that the fundamental pulmonic lesion is an acute interstitial pneumonitis essentially similar to influenzal pneumonitis uncomplicated by secondary bacterial invaders and to measles pneumonitis. His cases came in the

main from army hospitals, but there were also civilian cases both from this country and from abroad. The pathologic process centers about the bronchioles, which are filled with pus and desquamated cells from the lining, which is partially or completely destroyed. The bronchiolar walls are edematous and heavily infiltrated with round cells, in association with lymphocytic accumulation in the regional alveolar walls. In contrast to bacterial pneumonia, the alveolar spaces frequently contain air, although there is considerable variation of alveolar content. Others may contain edematous fluid and hyaline material as well as blood but not frankly purulent exudate. Such lung sections do not as a rule reveal micro-organisms on appropriate staining. In some bronchiolar lumens a mixed bacterial flora suggests contamination from the upper respiratory passages. Secondary bacterial invasion may produce typical bronchopneumonia, lobar pneumonia even lung abscess, much as occurred in the last influenza pandemic. Grossly the lungs of "atypical pneumonia" resemble an acute milary granulomatous process. The whitish "milium" in reality are bronchiolar swellings from which pus is easily expressed. The paucity of the physical signs and the spotty x-ray appearance are explained by the character of the pulmonary involvement. Unless x-ray views of the lungs are taken routinely and interpreted correctly, cases of atypical pneumonia may fail of recognition. Hemorrhagic encephalitis has been observed by Perrone and Wright⁶ and also by Golden⁵.

So far treatment has been symptomatic only. Neither sulfonamides nor penicillin has influenced the course. As yet there is no information available about the sequelae or complications, although bronchiectasis has been mentioned as a possible sequel.⁷

The death rate in uncomplicated primary atypical pneumonia has remained low, at a fraction of 1 per cent.

MEDICINAL USE OF DETERGENTS

Some of the detergents recently developed by industry and incorporated into soaps, shampoos, dentifrices, creams and foodstuffs are being used more and more as germicides, as cleansing agents of intact and ulcerated skin and as penetrants aiding in the resorption of therapeutically active substances through the skin and mucous membranes. They have been tried also as inactivators of pepsin in the treatment of gastroduodenal ulcer¹ and of trypsin in the management of chronic ulcerative colitis,² as inhibitors of peritoneal adhesions and as thrombotic and sclerotic agents in

varicose veins³ But few investigations have dealt with the mechanism of their biologic action and with their local and systemic toxicity

There are anionic, cationic and nonionic detergents and, apart from the chemical composition, the predominant electric charge of these agents determines their biologic action, especially on the physicochemical status and colloidal equilibrium of the cells and tissue fluids The high germicidal properties of the cationic detergents prove that biologically they are highly active Some of the detergents when given orally display a cumulative effect Their biologic and toxic effects are attributed to interference with cellular respiration denaturation of proteins and derangement of the lipoidal cellular structures⁴ Toxicity studies show that some cause local necrosis when given subcutaneously or intramuscularly Intravenous injection is followed by a drop in blood pressure and hemolysis, such as occur after the introduction of lecithin and salts of bile acids In animals prolonged oral medication with these agents resulted in degenerations of the kidney, diarrhea and hyperemia and hemorrhages in the intestinal mucosa⁵ Similar intestinal effects were observed in man The inhibition of the gastrointestinal proteolytic enzymes as well as an increased permeability of the gastrointestinal wall seems to be involved in the production of these symptoms

The medicinal and particularly the internal use of detergents appears to be still in the experimental stage Much more intensive study is needed before they can be included in the list of useful medical substances for application internally

A COMMON FACTOR IN INFECTION AND FERTILIZATION

The steady advances of biochemistry and immunology have been disclosing the presence of the same complex compounds, some of them being known as possessing remarkable physiologic effects, in apparently unrelated living entities Omitting vitamins and the common enzymes, the cases of some sex hormones, cardiac glucosides and the Forsman antigen may be suggested as representative examples

Recently another interesting example involving a system of a powerful enzyme and its specific substrate has been added to the list Hyaluronidase, best known and most important of the "spreading factors,"¹ is present abundantly in invasive bacteria such as staphylococci pneumococci and some anaerobic gas gangrene

bacteria, in the poisonous secretions of snakes and insects, in leeches and in the testes and sperms of mammals By hydrolyzing hyaluronic acid present in the cement between the cells of the connective tissues, the gelatinous fundamental substance of the mesenchyme, the enzyme brings about a spreading throughout the tissues of any particulate matter inoculated along with it and hence of the bacteria themselves that secrete the enzyme

It has been known for several years - that the arrival of spermatozoa in the area surrounding the mammalian tubal ova is followed by a disaggregation of the cumulus cells and corona radiata surrounding the ovum this phenomenon being a practically indispensable preliminary step for fertilization It was also known that the cumulus cells are embedded in a transparent viscous material, as Long² showed in 1912 Manipulation of these cells reveals the sticky nature of the intercellular cement The freeing of ova from the protective cells is accomplished by extracts of sperm not only from homologous but also from heterologous species -

In 1942 two independent teams of workers, McClean and Rowlands⁴ in England and Fekete and Duran-Reynals⁵ in this country, discovered in rats and mice respectively that the addition to ova kept in vitro of a variety of materials known to be rich in hyaluronidase resulted in the prompt disaggregation of the cumulus oophorus cells Highly purified preparations of testis hyaluronidase, if used in high concentrations, leave the ovum free from surrounding cells in sixty seconds

Recently Rowlands⁶ has found that in female rabbits previously treated with chorionic gonadotropin and inseminated with titrated suspensions of homologous spermatozoa to which hyaluronidase has been added the amount of spermatozoa needed to ensure fertilization is one sixth less than in controls inseminated without addition of the enzyme These experiments throw light on the amount of sperm required to be inseminated in order that one or a few spermatozoa may reach the ova in the fallopian tube and suggests an explanation for infertility associated with oligospermia

For many years embryologists have been eagerly looking for chemical components in sperm capable of bringing about individually a few at least of the marvelous effects that the intact spermatozoon does after entering the ovum All these efforts have failed Although not concerned with fertilization in the strict sense of the term the hyaluronidase effect can be considered as a step in this direction Other interesting contributions in this regard are those of Tyler⁷ on the specific interacting substances of eggs and sperm in lower marine animals and the unexpected analogies

between these effects and the antigen-antibody reactions of orthodox immunology

That the cement between the cumulus cells, like the fundamental substance of the connective tissue, has hyaluronic acid as its main or only component may not be surprising. However, the same enzyme in the poison of rattlesnake venom or the secretion of *Clostridium welchii* is responsible for the brutal effects of these materials. In other words, the same enzyme substrate system is of a basic importance in two biologic processes as different from each other as infection and reproduction.

REDUCTION IN SIZE OF ARMY MEDICAL CORPS

The Medical Corps of the Army will be slightly reduced in size in the near future. The statement by Surgeon General Kirk elsewhere in this issue explains that a moderate reduction in the number of Medical Corps officers is necessary if the Medical Department is to remain within the currently allotted ceiling for personnel. At present the need for senior administrative officers is less than it was earlier in the war. Many factors are considered in the release of medical officers, such as physical fitness, age, professional competence and available positions. To provide proper consideration of the qualifications of a man in relation to his essentiality in the war effort, a board of officers was recently appointed by the Office of the Surgeon General to review each case. The board after suitable study will no doubt recommend a number of separations from the service.

Regular Medical Corps officers will be accorded retirement privileges under Army Regulations, and Reserve National Guard and Army of the United States Medical Corps officers will be given the opportunity of returning to the civilian practice of medicine by relief from active duty or discharge. If the men chosen to be released from service are carefully selected, much information may be gained useful for later demobilization.

Some have mistakenly thought that physicians are no longer being commissioned by the Army following the ceiling registration of Medical Corps officers. The Current Comment of the November 4 issue of THE JOURNAL called attention expressly to

the announcement by the War Department and by the War Manpower Commission that recruitment of civilian physicians for the Army has been discontinued. The Navy requires 3,000 additional officers at once. The Army is to fill its future requirements from the young men who complete their medical education and internships.

The Army will continue to appoint all physically qualified recent graduates from medical schools. There is no indication that it will deviate from that policy. Men trained under the Army Specialized Training Program will be required to enter active duty with the Army immediately on the completion of their hospital training. Civilian physicians who are declared available by the Procurement and Assignment Service will however, be urged to seek commissions in the Navy. The need for young physicians as medical officers is still great.

Current Comment

THE CHILDREN'S BUREAU MAKES NEW REGULATIONS REGARDING SERVICES TO THE CRIPPLED

The Children's Bureau in November 1944 amended its regulations relating to services for crippled children by adding the following provisions: "Effective July 1, 1945 it shall be a condition of approval of a plan that it provide that diagnostic services will be made available thereunder to crippled children without restrictions as to race, color, creed, economic status, legal residence, age (except as to persons above the maximum age for which such services are legally available within the state), the necessity of referral by any person other than the child's parents or legal guardian, or similar restrictions inconsistent with the free availability of such services."¹ In December the Medical Advisory Council of the Indiana University School of Medicine pointed out that the acceptance of any child for diagnosis without restriction as to economic status and the referral of children by the parents or legal guardian only are in conflict with the established policy of the Indiana University Medical Center. The Advisory Council therefore requested the Board of Trustees of Indiana University to authorize the Indiana University Medical Center to withdraw from participation in the Crippled Children's Program of the Indiana State Department of Public Welfare whenever this new regulation is put into effect. At the same time it resolved that the Indiana University Medical Center continue to receive crippled children for diagnosis and treatment under the welfare hospital commitment program, so that no eligible and needy child would be denied clinic or hospital examination and treatment. The ruling of the Children's Bureau in eliminating any means test in the giving of governmental services for the care of the sick would seem to be in accord with repeatedly expressed policies of that agency in regard to most of the other services that it renders. More than ever the desirability that the health and medical activities of the government be coordinated under a single agency is apparent.

COLLOIDAL PLASMA SUBSTITUTES

The wide acceptance of human plasma as the most effective colloidal agent in the treatment of traumatic shock has exerted a restraining influence on the clinical use of the various colloidal plasma substitutes (gelatin, isinglass, pectin, methylcellulose, polyvinyl alcohol, vinyl pyrrolidone polymer), recently developed. Properly prepared solutions of these hydrophilic colloids have certain advantages over plasma. They are relatively inexpensive, readily available in large quantities and in sufficiently pure form, and nonantigenic. Several of these agents (methylcellulose, polyvinyl alcohol) are not easily contaminated with micro-organisms, pathogenic or nonpathogenic, and do not undergo any appreciable physicochemical changes on autoclaving. The

¹ The amendment is made to section 1102, 49 Stat. 647, 42 USC 1302, Sec. 513, 49 Stat. 632, as amended by Sec. 506, 53 Stat. 1181, 42 USC 713.

neutral solutions of gelatin, isinglass and pectin, on the other hand, suffer molecular degradation when subjected to heating and therefore alter the degree of dispersion, viscosity and colloid osmotic pressure. As the colloid plasma substitutes have filamentary molecules and not globular ones, like the plasma albumins and globulins, they differ from these in osmotic and viscous properties. Extensive clinical use of these agents has been hindered by certain undesirable effects on the recipient. They cause a conglomeration and increased sedimentation of erythrocytes. They do not furnish any material for the restoration of lost plasma proteins and may, when introduced in excessive amounts, interfere with the production of plasma proteins in addition to causing anemia. These untoward sequelae result in part from the retention of some of the injected colloidal matter in the internal organs, particularly the liver, as observed after the administration of methylcellulose with an average molecular weight as low as 33,000. Although the therapeutic effect of these agents is attributed to the same mechanism as is the effect of plasma, the therapeutic results after the experimental and clinical administration of the substitutes vary greatly in different investigations and in the type and stage of shock treated. For these reasons the recent work by Locke¹ and by Roome and his associates² is noteworthy. After the injection of a solution of a polyvinyl alcohol of a low molecular weight (14,000) into animals in experimental shock they obtained survival rates considerably better than after the administration of plasma. The additional claim is advanced that this material is not retained in the internal organs because of its relatively small molecular size, permitting its escape through the vascular membranes. These observations revive the hope that the search for the ideal plasma substitute is still a promising field of scientific endeavor.

ESCAPE OF EASILY DETACHABLE BLOOD IRON

An increase in the iron content occurs in certain tissues and yet iron is not demonstrable in them by the conventional methods of study. Sheldon's³ suggestion that this might be due to an increase in "physiologic" iron not stainable by the usual methods is supported by the recent work of the Popoffs² of the Genesee Hospital, Rochester, N. Y. With a new technic they found that iron invisible with ordinary methods was easily demonstrated. The technic is based on the fixation of thin pieces of tissues in a solution of toluidine blue, formaldehyde and acetone, and on subsequent treatment with acetic acid-zinc sulfate mixture. This iron, which may be of importance in a number of conditions, represents apparently a labile form of blood iron. It detaches itself from the erythrocytes rapidly and is taken up immediately by mesenchymal and epi-

thelial cells. For example, iron can be demonstrated in the epithelial cells of thyroid follicles one hour after the start of thyroidectomy. While the uninjured parts of the gland do not show even traces of iron, the traumatized areas show massive accumulation of iron granules in endothelial cells, epithelial cells and local histiocytes. Studies of other human material indicate that detachment of iron with consequent deposition occurs in many conditions such as postoperative shock, death due to ether anesthesia, thrombosis, myocardial infarction, pulmonary infarction and pneumonia. Most striking is the siderosis found in congestive heart failure. With the usual methods of staining, hemosiderin is found in alveolar phagocytes here and there but the histologic preparations give no idea of the actual amount of abnormal iron in the lungs. With the new technic practically all septal cells of the lungs are found to be loaded to capacity with iron granules. One sees even mucus secreting cells of the bronchi blocked with iron. In hemochromatosis repeated discrepancies have been observed between the amount of iron found chemically and that demonstrated histologically. The new technic shows that this is due to the failure of old methods to demonstrate all the iron in the tissues. In hemolytic anemia of the newborn in addition to other tissues a particularly extensive siderosis was found in the hypophysis, both chief and alpha cells being loaded with iron. From these studies a siderosis of this kind appears to be an intravital phenomenon due probably to anoxia from interference with local circulation. Experimental investigations support this concept. When venous stasis of the extremities is produced in animals local siderosis develops promptly, iron being found in the endothelial, muscular and perithelial cells within three hours after interference with circulation. Three forms of blood iron are now recognized, namely hemoglobin iron, plasma iron and an easily detachable form of iron which, according to the pioneer work in this field by Barkan³ and by Lintzel⁴ constitutes about 10 per cent of the total blood iron. An organic compound, this iron differs from the ordinary iron in being ionized and dialyzable. The research reviewed indicates that this iron may play an important part in pathologic processes which merits further investigation.

EDITOR OF THE LANCET

Dr Egbert Morland, who joined the staff of the London *Lancet* in 1915 and who became its editor in 1937, has just retired as editor. He is succeeded by Dr T. F. Fox. Under Dr Morland the *Lancet* maintained its standard of editorial content. He did much to aid the advancement of medical science and practice in Great Britain. His achievements as editor of the *Lancet* were recognized by both the Royal College of Physicians and the Royal College of Surgeons, who admitted him to fellowship. *THE JOURNAL* felicitates Dr Morland on his career.

MEDICINE AND THE WAR

ARMY

PROGRESS IN PROGRAM FOR MEDICAL HISTORY

According to a report from Col Albert G Love, historian of the Army Medical Department, plans have been made to complete the writing of the medical history of the present war six months after victory in the Pacific. Several officers are now assigned to the historical program, approximately half of them serving in overseas theaters. Most of these officers hold graduate degrees in history from leading universities throughout the country. They were commissioned in the Medical Administrative Corps following completion of training in officer candidate schools. These officers are working on the administrative aspects of the medical service, including supply, personnel, training and hospital construction. The professional medical experience of the Army will be recorded by medical officers especially qualified in various specialties.

Previous histories published by the Medical Department appeared several years after the cessation of hostilities. Twenty-three years was required to complete the medical history of the Civil War, ten years to complete that of the first world war. At a meeting of historical officers held in the office of the Surgeon General on December 6, announcement was made that sufficient volumes would be published to cover the entire scope of the Medical Department's professional and administrative work.

REDUCTION IN THE MEDICAL CORPS OF THE ARMY

The Office of the Surgeon General recently announced that a moderate reduction in numbers of Army Medical Corps officers is necessary in order to remain within the present allotted ceilings. The need for medical corps officers in senior grades who are assigned principally to administrative duties is less acute than formerly. A board of officers recently appointed in the Office of the Surgeon General is carefully considering the physical and other qualifications of all medical corps officers of the various components of the Army and their essentiality to the war effort. As a result of this board's study, it is anticipated that a number of separations of the aforementioned group will occur in the near future. Regular medical corps officers will be accorded retirement privileges under the provisions of section II, Ar 605-245 June 17, 1941 and Reserve, National Guard, and A U S Medical Corps officers will be given the opportunity of returning to the practice of medicine in a civilian status by relief from active duty or discharge.

COL ALBERT E McEVERS COMMANDING OFFICER AT BILLINGS GENERAL HOSPITAL

Col Albert E McEvers, formerly commanding officer of the ASF Oakland Regional hospital, was recently appointed commanding officer of Billings General Hospital, Fort Benjamin Harrison, Indiana. An army surgeon veteran of three wars, Dr McEvers first saw action on the Mexican border in 1916 and served as a surgeon during the major offensive at Aisne-Marne, St Mihiel, the Neuse-Argonne, Champagne and Meuse-Champagne during the first world war. After returning to the United States he was appointed major in the Officers Reserve Corps and practiced in Chicago and Los Angeles until the outbreak of the present war. He received his full rank of colonel in the medical reserve in 1934. In September 1939 he accepted reappointment to this rank.

PROMOTED TO BRIGADIER GENERAL

The War Department recently announced the temporary promotion of Col John A Rogers, formerly of Nashua, N H, to the rank of brigadier general.

ARMY AWARDS AND COMMENDATIONS

Captain Robert J Sating

The Silver Star for "Distinguished Gallantry in Action" in an undisclosed campaign in the Mediterranean theater was awarded to Capt Robert J Sating, formerly of Cleveland Heights, Ohio. Previous to his award Dr Sating received a Certificate of Commendation from the commanding general of the 9th Division, dated May 13, 1944, which read: "Certificate of Commendation. For outstanding and especially meritorious service, this Certificate of Commendation is awarded to Capt Robert J Sating, M C, 84th Field Artillery, 9th Division. Capt Sating for two days and nights attended the wounded of two American artillery battalions and a British brigade. Working tirelessly, he was conspicuous by his courage and self sacrifice. His work materially reduced the fatalities among both American and British wounded. His actions were clearly indicative of high military standards." Dr Sating graduated from St Louis University School of Medicine in 1937 and entered the service July 31, 1941.

Captain Roscoe I McFadden

The Bronze Star Medal was recently awarded to Capt Roscoe I McFadden, formerly of Madison College, Tenn. The citation read: "During an intense enemy artillery barrage on April 6, 1944 near Anzio, Italy, a detachment tent of a hospital was struck by an enemy shell. With other medical officers who were on duty with him at an adjacent hospital he immediately rushed to the scene of the shelling and administered treatment to a number of seriously wounded soldiers. Although the area was under continuous bombardment they remained at the perilous task of rendering medical aid and expediting the quick removal of casualties for additional treatment. Their heroic performance reflects the finest traditions of the Medical Corps. Dr McFadden graduated from the College of Medical Evangelists, Loma-Linda, Calif, in 1940 and entered the service March 20, 1941.

Captain Ralph L Phillips

The Bronze Star Medal was recently awarded to Capt Ralph Phillips, formerly of Columbus, whose citation states that "on March 14, 1944 at Bougainville, Solomon Islands, he unhesitatingly crawled through an open area under intense machine gun fire to give medical aid to several soldiers and a wounded officer. His courage and alert action inspired other members of the patrol, who dispersed the enemy killing four and taking one prisoner." Dr Phillips graduated from Ohio State University College of Medicine, Columbus, in 1942 and entered the service Aug 1, 1943.

Major Saul Greizman

The Legion of Merit was recently awarded to Major Saul Greizman, formerly of Pittsburgh, for "exceptionally meritorious conduct in the performance of outstanding service in the Solomon Islands from July 22, 1943 to April 7, 1944." Dr Greizman who was born in Romanov, Russia, graduated from Vanderbilt University School of Medicine, Nashville, Tenn, in 1935 and entered the service in 1942.

Captain Eugene Haverty

Posthumous awards were recently bestowed on Capt Eugene Haverty, formerly of Pittsburgh. The Silver Star was awarded for exceptional gallantry in action and the Legion of Merit, which is rated as one of the highest medals of honor, was awarded for exceptionally meritorious service on the Italian front. Dr Haverty graduated from Georgetown University School of Medicine, Washington, in 1938 and entered the service July 7 1941.

NAVY

TRANSFER TO REGULAR NAVY OF
RESERVE OFFICERS

Secretary of the Navy James Forrestal recently appointed nineteen members and a recorder to consider and make recommendations for the transfer to permanent commissioned rank in the U S Navy of Naval Reserve and temporary officers. The Secretary of the Navy also asked the board to "make a comprehensive study of the employment, assignment and relationship of Reserve and temporary officers with officers of the Regular Navy." The board will submit a report to the chief of naval personnel, Vice Admiral Randall Jacobs, who in turn will forward the findings to the Secretary of the Navy. All members are now on duty in Washington. The Medical Corps members of the board are Capt. Thomas B. Magath, Rochester, Minn., and Comdr. Louis M. Harris, San Antonio, Texas.

FLEET HOSPITAL NO 113 COMMISSIONED

Fleet Hospital No 113, a 2,000 bed enlarged copy of mobile units now in operation at advanced Pacific bases, was recently commissioned by the Navy in San Francisco. The new installation, the first of its type to be established in the United States, was erected in less than four months. It consists of 255 fifty foot steel buildings including surgical, medical and neuropsychiatric wards, administration buildings, postoffice, laundry, galley and mess halls, operating rooms, laboratories, x-ray and dental departments, corpsmen's and nurses' quarters, garage and maintenance buildings. Among recreational facilities are basketball and tennis courts, horseshoe pits and a hall for indoor sports.

Rear Admiral Carleton H. Wright, commandant of the 12th Naval District, was principal speaker at the commissioning ceremonies. Rear Admiral Edgar L. Woods, Pacific Coast inspector of medical department activities and Rear Admiral Daniel Hunt, district medical officer, also participated in the

ceremonies. Capt. Gerald W. Smith, Navy Medical Corps, is commandant.

Virtually all Navy and Marine Corps casualties returning from the Pacific will be received at the new hospital. Ambulances will meet hospital ships and transports. Treatment will supplement that given at the front aboard hospital ships and at base and fleet hospitals. The new installation will also serve to train medical officers, hospital corpsmen and nurses.

NAVY AWARDS AND COMMENDATIONS

Captain Frederick C. Greaves

Capt. Frederick C. Greaves, formerly of Villesca, Iowa, has been awarded a Gold Star in lieu of a second Bronze Star Medal. The citation accompanying the award reads: "For distinguishing himself by meritorious services as medical officer on the staff of a major naval task force commander prior to and during the amphibious invasion of southern France in August 1944. Captain Greaves, exercising professional skill to a high degree, developed sound and workable casualty evacuation plans setting up procedures by which casualties were expeditiously cleared from the assault beaches and evacuated to base hospitals. His able and thorough efforts in supervising the work of fitting out landing craft as hospital carriers, in improving medical facilities in combat loaders and in coordinating the scheduling of hospital ships to and from the assault area contributed materially to the effective and prompt manner in which all army and naval casualties were handled during the Allied invasion of southern France. The extraordinary skill, sound judgment and outstanding devotion to duty displayed by Captain Greaves reflected credit on himself and the naval service." Dr. Greaves graduated from the State University of Iowa College of Medicine, Iowa City, in 1920 and entered the service May 26, 1923.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL December 16, page 1035)

CALIFORNIA

Permanente Foundation Hospital, Oakland. Capacity 136 admissions, 3,693. Dr. Sidney R. Garfield, Superintendent (interns July 1945).

NEW YORK

Crouse-Ingersoll Hospital, Syracuse. Capacity 245 admissions, 7,035. Miss Dorothy Pellenz, Assistant Superintendent (interns).

OKLAHOMA

St. Anthony's Hospital, Oklahoma City. Capacity, 450 admissions, 13,017. Sister M. Mechtildis, R.N., Superintendent (2 interns, 1 resident—orthopedics).

VIRGINIA

Grace Hospital, Richmond. Capacity, 100 admissions, 4,135. Mr. R. H. Thomas, Managing Director (2 residents—mixed).

WASHINGTON

Pierce County Hospital, Tacoma. Capacity, 239 admissions, 3,032. Dr. Burton A. Brown, Administrator (3 interns, July 1, 1945).

WARTIME GRADUATE MEDICAL
MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Mayo General Hospital, Galesburg, Ill. Plexus and Peripheral Nerve Injuries. Major Frank A. Mayfield, January 3.

Camp Ellis, Illinois. Endocrinology, Dr. Willard O. Thompson, January 3.

Chanute Field, Rantoul, Ill. Heart Disease and Allied Conditions, Drs. Newell C. Gilbert and George Karl Fenn, January 3.

Vaughan General Hospital, Maywood, Ill. Malignancies in the Army Age Group. Medical X-Ray and Surgical Diagnosis and Treatment, Drs. Max Cutler and George J. Rukstnat, January 3.

Gardner General Hospital, Chicago. Laboratory Diagnosis and Its Relationship to Medical and Surgical Treatment, Drs. William S. Hoffman and Steven O. Schwartz, January 3.

Fort Sheridan, Ill. Brain and Spinal Cord Injuries, Drs. Adrien H. P. E. Verbrugghen and Paul C. Bucy, January 3.

Society Proceedings

COMING MEETINGS

Annual Congress on Industrial Health, Chicago, Feb. 13-15. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago, Secretary.

Annual Congress on Medical Education and Licensure, Chicago, Feb. 12-13. Dr. Victor Johnson, 535 N. Dearborn St., Chicago, Secretary.

Annual Forum on Allergy, Pittsburgh, January 20-21. Dr. Jonathan Forman, 926 Bryden Road, Columbus, Ohio, Director.

Eastern Section, American Laryngological, Rhinological and Otolological Society, Philadelphia, January 12. Dr. Oram R. Kline, 414 Cooper St., Camden, N. J., Chairman.

Middle Section, American Laryngological, Rhinological and Otolological Society, Indianapolis, January 17. Dr. Carl H. McCaskey, 608 Guaranty Bldg., Indianapolis, Chairman.

Society of Surgeons of New Jersey, Jersey City, January 31. Dr. Walter B. Mount, 21 Plymouth St., Montclair, N. J., Secretary.

Southern Section, American Laryngological, Rhinological and Otolological Society, Charlotte, N. C., January 15. Dr. Verling K. Hart, 106 W. 7th St., Charlotte, N. C., Chairman.

Western Section, American Laryngological, Rhinological and Otolological Society, Los Angeles, January 27-28. Dr. Aubrey G. Rawlins, 384 Post St., San Francisco, Chairman.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Edward Kupka Named to New Position—Dr Edward Kupka, Los Angeles, recently chief of the bureau of tuberculosis of the California State Department of Public Health has been elected medical director of the La Vina Sanatorium, La Vina, and the Hastings Foundation for Tuberculosis Research, Pasadena, to succeed Dr Carl R Howson, who resigned, effective January 1, to devote his full time to private practice. The foundation is currently erecting the Charles Cook Hastings Home, which will house its sanatorium and research functions on ground adjacent to the La Vina Sanatorium in the foothills north of Pasadena (THE JOURNAL, March 25, p 937 and May 23, 1942, p 356)

Auxiliary Holds Fair for Physicians' Aid—On December 8 the Woman's Auxiliary to the Los Angeles County Medical Association sponsored a fair in the ballroom of the Elks' Club, Los Angeles, for the benefit of the Los Angeles County Physicians' Aid Association. Edmund Lowe acted as master of ceremonies, and featured guests included Edgar Bergen. Members of the Los Angeles County Medical Association volunteered their services, and the entertainers included Dr Rudi Lederer as a pantomimist. A "Century Dinner" preceded the fair, which marked the opening of the aid association's list to contributions from lay persons in its campaign to raise \$100,000, one fifth of the amount ultimately planned.

Postgraduate Symposium—The Los Angeles Heart Association presented its fourteenth annual postgraduate symposium on heart disease December 6-7, at the Los Angeles County Medical Association. The guest speakers included

Dr Arthur C DeGraff, New York, Uses and Abuses of Mercurial Diuretics
Capt William H Leake (MC), Rheumatic Fever Problem in the Navy
Lieut Comdr George C Griffith (MC), Clinical Aspects and Treatment of Rheumatic Fever
Lieut Comdr Robert W Huntington (MC), Current Concepts of Pathogenesis as Illustrated by Pathologic Changes in Rheumatic Fever
Lieut Hugh R Butt (MC), Physiologic Effect of Sodium Silylate in the Human with Particular Reference to the Prothrombin Level in the Blood and the Hepatic Parenchyma

The annual dinner was addressed by Dr DeGraff on "Present Status of Digitalis and the Cardiac Glucosides in the Treatment of Congestive Heart Failure."

CONNECTICUT

Industrial Health Conference—On December 14 an industrial health conference was held at the Hotel Taft, New Haven, under the auspices of the committee on industrial health and safety of the Manufacturers' Association of Connecticut and the committee on industrial health of the Connecticut State Medical Society. Among the speakers were Dr Martin I Hall, Bristol, Dr Philip J Moorad, New Britain, and Carl Schedler, director of industrial relations, Torrington Company, Torrington, who participated in a panel discussion on "The Physically and Mentally Handicapped Worker." Edward Chester, supervisor, Vocational Rehabilitation, Connecticut State Department of Education, Hartford, and Stanwood L Hanson, assistant vice president, Liberty Mutual Insurance Company, Boston, presented a panel discussion on rehabilitation services and William H Heimrick, Travelers Insurance Company, Hartford, and Allen L Coleman, chief industrial hygienist, Bureau of Industrial Hygiene, Connecticut Department of Health, Hartford, one on "Safeguarding the Industrial Worker." Dr Creighton Barker, New Haven, secretary Connecticut State Medical Society, was toastmaster at a dinner at which Governor Raymond E Baldwin and Alfred C Fuller, Hartford, president, Manufacturers' Association of Connecticut, spoke and Col Anthony J Lanza, M C, discussed "Postwar Development of Industrial Health Services."

DELAWARE

Society News—Dr Emory Burnett, professor of clinical surgery, Temple University School of Medicine, Philadelphia, addressed the New Castle County Medical Society in Wilmington November 21, on "Modern Thoracic Surgery in Civilian Practice."

FLORIDA

Joint Meeting on the Heart—On November 7 the Miami Heart Association and the Dade County Medical Association held a joint meeting at the James M Jackson Memorial Hospital, Miami, to hear the following speakers:

Dr Maurice A Kugel, Miami Beach, Acute Coronary Occlusion and Myocardial Infarction Without Pain
Lieut Col Gilbert H Marquardt and Capt Julian S Butterworth, M C, Coronary Disease in Young Adults
Drs Edward Sterling Nichol and Samuel W Page, Miami, Use of Dicumarol in Acute Coronary Occlusion

GEORGIA

University News—Frederick Stearns and Company has made a grant of \$1,800 to establish for the coming year at the University of Georgia School of Medicine, Augusta, a fellowship in pharmacology for the investigation of uterine antispasmodics. The chancellor and board of regents of the university have provided funds for creating additional clinical departments for the eye, ear, nose and throat and plastic surgery.

ILLINOIS

Hospital News—Ground was broken for a new hospital building to be erected as an addition to the Presbyterian Home, Evanston. The new wing will cost around \$400,000, and the WPB has granted all necessary priorities for the work.

Chicago

University News—Dr Rafael Mendez, formerly instructor in pharmacotherapy, Harvard Medical School, Boston, has been promoted to associate professor and appointed acting chairman of the department of pharmacology at Loyola University School of Medicine, effective January 1. He fills the vacancy that occurred when Dr Amedeo S Marrazzi went to Wayne University College of Medicine, Detroit (THE JOURNAL, October 7, p 376).

LOUISIANA

Personal—Henry Laurens, Ph D, has resigned as professor of physiology at Tulane University of Louisiana School of Medicine, New Orleans.

Medical Society Plans Business Meeting in 1945—At a meeting of the executive committee of the Louisiana State Medical Society on November 11 it was decided that a one day business session of the house of delegates will be held in New Orleans April 13. A scientific session is not planned.

MARYLAND

Personal—Mrs Florence J Neely, B A, has been appointed chief of the newly organized division of nutrition in the bureau of food control of the Baltimore City Health Department effective October 30.

Society News—Dr James Howard Means, Jackson professor of clinical medicine, Harvard Medical School, Boston, addressed the annual meeting of the Baltimore City Medical Society, December 8, on "Hyperophthalmopathic Graves Disease."

MICHIGAN

Fellowships in Pharmacology—The department of pharmacology of Wayne University College of Medicine, Detroit, announces that two teaching fellowships are immediately available for students who wish to obtain the master of science degree in pharmacology. The fellowships carry a yearly stipend of \$1,424 apiece. Address application and inquiries to Dr Amedeo S Marrazzi, professor and chairman of the department of pharmacology, 1512 St Antoine, Detroit 26.

Personal—Merrill C Hart, Sc D, has been appointed a member of the board of directors, vice president and director of research of the Upjohn Company, Kalamazoo, to succeed Frederick W Heyl, Sc D, effective December 1.—Dr George D Woodward, Jackson, psychiatrist at the Southern Michigan Prison Hospital, has been appointed superintendent of the new branch mental hospital at Sault Ste Marie, where the first patients will be installed soon. The new appointment will be effective January 1.—Dr George M Livingston, Detroit, has been given honorary membership in the Wayne County Medical Society.

Special Society Elections—Dr David Littlejohn, director of the Wayne County Health Department, was chosen president-elect of the Michigan Public Health Association during its meeting in Grand Rapids, November 8-10. Nathan Sinai, DPH, Ann Arbor, was installed as president. Other officers include Pearl L Kendrick, Sc D, director of the western Michigan Division Laboratory, state department of

health, Grand Rapids vice president and Marjorie Delavan, Lansing, director of the bureau of education of the state department of health, secretary-treasurer—Dr John J. Pollack was recently chosen president of the Detroit Pediatric Society, Dr Philip J. Howard is secretary.

New Community Hospital Opened—On December 15 the People's Community Hospital, Western Wayne County, was scheduled to be formally opened. The project is a realization of a plan to make available beds at the Eloise Hospital and Infirmary, Eloise, for patients of private physicians. The three story building has been leased from the county for the duration of the war and six months thereafter. Of the 71 beds, which double the previous capacity, 25 are for obstetric and 46 for general purposes. There are 33 bassinets, 2 delivery rooms, 2 nurseries, 1 isolation nursery and 1 isolation bed for mothers. The project is one sponsored by the Wayne County Medical Society. The cost was about \$125,000 for construction and \$36,000 for equipment. \$15,000 was contributed by the People's Community Hospital in voluntary contributions and the remainder was borne by the federal government on approval of the federal works agency. The People's Community Hospital is a nonprofit Michigan corporation incorporated Jan. 6, 1943 to "construct, maintain and conduct a hospital." The project originated among the medical profession of western Wayne County when conditions became acute two to three years ago. The corporation plans after the war to construct a major hospital near the vicinity of Wayne, which is the center of the district to be served, and to construct smaller hospitals for minor procedures and convalescence in the various thickly populated communities of the general area (THE JOURNAL, May 27, p. 295).

NEW YORK

Changes in Health Officers—Dr Joseph H. Kinnaman, Ponca City, Okla., director of the Kay County Health Department of Oklahoma, has been appointed deputy commissioner of health of Nassau County, succeeding Dr William H. Runcie, Freeport, who retired last April.

Human Death from Rabies—The first case of human rabies to occur in upstate New York since 1930 was reported recently in Sheridan, Chautauque County, where canine rabies has existed for the past year, according to *Health News*. The victim, a 60 year old farmer, contracted the illness as the result of having been bitten on August 13 by a rabid dog owned by his family. He died in a Dunkirk hospital, November 9.

New York City

Physicians' Home—A sum of \$5,919.25 was expended for the maintenance of beneficiaries of the Physicians' Home according to the annual financial report of the home which has recently been published for the year Oct. 1, 1943–Sept. 30, 1944.

Vincent du Vigneaud Awarded Nichols Medal—Vincent du Vigneaud, Ph.D., professor and head of the department of biochemistry, Cornell University Medical College has been chosen to receive the William H. Nichols Medal of the New York section of the American Chemical Society for his work on biotin. Dr. du Vigneaud received his Ph.D. at the University of Rochester in 1927 and has been identified with Cornell since 1938. His discovery of the chemical properties of biotin was announced at a meeting of the New York section Oct. 9, 1942, and in 1943 the synthesis of biotin was achieved in the laboratories of Merck and Company, Rahway, N. J.

Club for Patients Who Have Lost Larynx—A club composed of 100 men and women who have had their larynx or speech organs removed has been organized at the National Hospital for Speech Disorders. The name of the club is Anamilo, Greek for "I speak again." A special committee of the club has been formed to call on the request of the attending surgeon, on patients in the metropolitan area who face removal of the larynx or have just had the operation. A patient who has had his larynx removed must learn to speak again, either by using a mechanical device comprising an artificial larynx or by substituting an esophageal voice.

Bacteriologist Honored by Ophthalmologists—Edgar B. Burchell, D.Sc., bacteriologist and attending serologist of the New York Eye and Ear Infirmary, was made an honorary fellow in the American Academy of Ophthalmology and Otolaryngology at special ceremonies December 14. According to the New York *Herald Tribune*, Mr. Burchell is the first person without an M.D. degree to be so honored by the academy. The *Herald Tribune* states that Mr. Burchell has never had more formal education than that supplied in the primary

grades of the New York City primary schools but has been called doctor since 1936, when he received the honorary degree of doctor of science from Roanoke College, Salem, Va. In 1931, when the king of Siam came to the United States to have a cataract removed by the late Dr. John M. Wheeler, Mr. Burchell was called in as consulting bacteriologist. Dr. William L. Benedict of the Mayo Clinic, Rochester, Minn., conferred the honorary membership on Mr. Burchell. Dr. Bernard Samuels, pathologist, presented the award and Dr. Clyde E. McDannald, senior surgeon in the eye department, was toastmaster.

Morrison Prizes Awarded—The two annual A. Cressy Morrison Prizes of \$200 each were presented December 14 to Eleanor G. Alexander-Jackson, Ph.D., member, research department of public health and preventive medicine, Cornell University Medical College, and Alexander Sandow, Ph.D., assistant professor of biology, Washington Square College, New York University, during the one hundred and twenty-seventh annual meeting of the New York Academy of Science at the American Museum of Natural History. The New York *Times* reported that this is the first time in the history of the prizes that one of them went to a woman scientist. Dr. Alexander-Jackson was chosen for her work in discovering a "hitherto unobserved form of the germ causing tuberculosis" revealing the existence of what is known as the "zooglyphic" form of tubercle bacillus. Dr. Sandow was selected for his paper reporting studies giving new light on the mechanism of muscular contraction. The Morrison Prizes are awarded "for the two most acceptable papers in any field of science, within the scope of the academy and its affiliated societies." Walter H. Bucher, Ph.D., was elected president of the academy of science. Dr. Florence R. Sabin, member emerita of the Rockefeller Institute for Medical Research, was elected an honorary life member, the first woman scientist to be thus honored by the academy.

OHIO

Physicians in Congress—Dr. Frederick C. Smith, Marion, was reelected to the U. S. Congress by the voters of the Eighth Ohio Congressional District on November 7. Two physician-members of the Ohio House of Representatives, Dr. Errett LeFever, Glouster, and Dr. Charles A. Craig, Cambridge, also were reelected. Dr. LeFever, unopposed this time, will be representing Athens County for the sixth time in the legislature. He has also served twelve years in the state senate. Dr. Howard V. Dutrow, Dayton, was unsuccessful in his campaign to become one of Montgomery County's representatives in the legislature. All four candidates are Republicans.

Hospital Tuberculosis Program—Eight hospitals in Cleveland will cooperate in a program to x-ray the chests of all employees and patients, beginning in January under the auspices of the Cleveland Hospital Council. According to *Ohio Public Health*, this is the first time for a group of hospitals to unite for such a purpose. The demonstration has been made possible through a gift of \$15,000 from the Cornelia W. Beardslee Fund of the Cleveland Clinic Foundation with the hospitals supplementing grants from this fund with money of their own to defray the cost. The participating hospitals are St. Vincent Charity City, University St. Alexis, Fairview Park, Huron Road, St. Luke's and Lutheran. Under the new program it is estimated that roentgenograms will be taken of about 100,000 persons.

Cincinnati University and Jewish Hospital Cooperate in Psychiatric Program—Dr. John Romano, professor of psychiatry at the University of Cincinnati College of Medicine, Cincinnati, will become director and chief of staff of a new department of psychiatry at the Jewish Hospital to be set up under the recent agreement with the medical school and the hospital. The agreement conforms with a four-point policy recently adopted by the university board to govern mutually advantageous affiliations between the college of medicine and local private hospitals, and the Jewish Hospital is the first to avail itself of the new policy. The hospital's agreement carries certain stipulations as to the management of the department, the choice of director and other members of the staff, emphasizing that the department shall be established and maintained by the hospital with not less than 25 per cent of free beds and adequate offices for the staff, interview rooms, laboratories and other facilities. The agreement also outlines the stipulations for the affiliation to the hospital and the university.

Dittrick Museum of Cultural and Historical Medicine—A special feature of the celebration of the fiftieth anniversary of the Cleveland Medical Library Association, November 26–27 (THE JOURNAL, November 4, p. 649) was the announcement that the Museum of Historical Medicine will in the future

be known as the Ditttrick Museum of Cultural and Historical Medicine in honor of Dr Howard Ditttrick, director of the museum and president of the library association, and Mrs Ditttrick, who have worked untiringly in developing the library's museum. At the jubilee dinner Dr Ditttrick was presented with an engrossed and illuminated scroll honoring him for his many years' service to the association, which has grown from its inception from a membership of about 80, an endowment fund of \$2,000 and a handful of books to one with a membership of about 1,300, endowments of more than \$600,000 a book collection of more than 62,000 and its own library building. Dr Ditttrick became curator of the museum in 1928 and in 1935 director. In 1943 he was presented with the Distinguished Service Award of the Academy of Medicine of Cleveland.

PENNSYLVANIA

Philadelphia

Fifty Years of Medicine—On January 9 the Medical Society of the State of Pennsylvania will honor the following members of the Philadelphia County Medical Society who have completed fifty years in the practice of medicine:

Dr William N. Bradley	Dr Frederic Hurst Maier
Dr Charles A. E. Codman	Dr Archibald L. McKinley
Dr Winslow Drummond	Dr John D. McLean
Dr William B. Griggs	Dr Gerald D. O'Farrell
Dr William O. Hermance	Dr George A. MacElree
Dr William F. Horn	(posthumously)

The guests will be entertained at a luncheon arranged by the first counselor district of the state society including the woman's auxiliary.

TENNESSEE

Frank Whitacre Joins Tennessee Faculty—Dr Frank E. Whitacre, who was in Manila on Pearl Harbor Day and who finally returned to the United States on the *Gripsholm* has been appointed associate professor of obstetrics and gynecology at the University of Tennessee College of Medicine Memphis, effective January 1. He has been given a full time appointment. Dr Whitacre formerly was instructor in obstetrics of a postgraduate committee at Tennessee, later going back to Peiping Union Medical College Peking. He was on his way back to America when he was caught in Manila Dec. 7, 1941.

Edward Turner Resigns at Meharry—Dr Edward L. Turner, who joined Meharry Medical College Nashville in 1936 as professor of medicine and became president of the college in 1938, has resigned his connection with the college to specialize in internal medicine at Bradford, Pa., effective January 1. M. Don Clawson, D.D.S., director of dental education at the Meharry Medical College since May 1942, has been named president to succeed Dr Turner. Other changes at the college include the appointment of Dr Murray C. Brown, Nashville, director of the local venereal disease control program who has been appointed director of medical education and will hold a professorship in medicine. Dr Turner graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1928, at the University of Chicago where he had received his M.S. degree in 1923 and at the American University of Beirut School of Medicine, Syria. Dr Brown graduated at the University of Virginia Department of Medicine Charlottesville in 1938.

VIRGINIA

Hospital Association Changes Name—The corporate name of the Richmond Hospital Association has been changed to the Virginia Hospital Service Association, according to the *Virginia Medical Monthly*. The change was made because the Blue Cross Plan for Hospital Care which started in 1935 for Richmond only is now serving seventy counties in central Virginia.

WEST VIRGINIA

Dr Hedrick Goes to Congress—Dr Erland H. Hedrick Beckley, has resigned as superintendent of the Pinecrest Sanatorium effective January 1 to take his seat in Congress, Washington, D. C., January 3. Dr Hedrick was elected by a majority exceeding 24,000 votes in the sixth district of West Virginia. He will retain his offices in Beckley, with a relief physician taking care of his practice during his absence.

WISCONSIN

Postgraduate Medical Courses—The University of Wisconsin Medical School, Madison, announces plans for refresher courses and postgraduate training for physicians returning from service and for those in civilian practice. Four plans have been set up: a refresher course of twelve weeks' duration, a two to six months course for specialists, residencies and basic science

training. The refresher course for general practitioners covers medicine, neurology and psychiatry, pediatrics, general surgery and allied specialties and obstetrics and gynecology. The course for specialists is open only to those who have already had training in their specialty and is designed as a review and refresher course in the various specialties. The division for residencies is for those who wish to acquire specialty training for certification, three year residencies in all of the specialties will be available. It is the plan to increase the number of residencies from a prewar number of approximately forty to approximately sixty. As in the past, in basic science training the preclinical departments are open to properly qualified men and women who wish to work for one year or more on any project in which they are interested. Additional information may be obtained from the dean of the medical school, University of Wisconsin, Madison.

Supreme Court Upholds Board of Health's Demurrer in Osteopath Case—In a decision rendered on October 10, the Wisconsin Supreme Court upheld the Wisconsin State Board of Health's demurrer to a suit attacking validity of excluding osteopaths from participation in the Emergency Maternal and Infant Care program, administered under the general direction of the Children's Bureau in Washington. Three osteopaths, representing 130 of them in the state, started the action after the board of health had prepared a plan for distributing the funds which excluded osteopaths from participation. The plan submitted to the Children's Bureau by the board of health limited participation to those licensed to practice medicine and surgery, based on a decision of the attorney general of Wisconsin that the board could by regulation define the qualifications of those permitted in the operation of the plan. The osteopaths attacked the board of health on the basis that its regulation imposed an arbitrary discrimination against osteopaths and was an exercise of a power not placed in the board in either state or federal statutes. The osteopaths asked for a declaratory judgment determining the validity of the rule and state plan particularly as it affected participation by the plaintiffs and other osteopaths. The board of health demurred in the circuit court on the ground that the complaint did not state sufficient facts to constitute a cause of action against it. The demurrer was overruled by the lower court and as a result the board of health appealed the case to the supreme court. In a decision written by Justice Joseph Martin the court concluded that the allegations of the complaint as well as the relief demanded, were solely concerned with the proper distribution of federal funds by a federal administrative board, through the Wisconsin State Board of Health acting as its agent. The several appropriations made by Congress to carry out the E. M. I. C. program were all made to the United States Department of Labor, Children's Bureau, which bureau allots the funds to the several states to carry out the program according to plans approved by the federal bureau. "That puts this controversy out of our reach," declared Justice Martin. "No facts are alleged in the complaint to the effect that any osteopath has been deprived of the right to practice obstetrics or that any such action has been threatened. Neither is any declaration demanded along this direction. The pleadings, therefore, state no cause of action for declaratory relief on this point, and it hardly needs to be said that this determination neither forecloses nor predetermines the merits of such an action."

GENERAL

Eric Johnston Named to Cancer Society—Eric A. Johnston, president of the U. S. Chamber of Commerce, has been elected chairman of the newly created executive council of the American Cancer Society and national chairman of the society's fund raising campaign next April.

Mental Hygiene Officers—Eugene Meyer, LL.D., editor and publisher of the *Washington Post* was elected president of the National Committee for Mental Hygiene at a meeting of its board of directors in New York, December 14. Mr. Meyer is the first layman to be chosen president of the National Committee in the thirty-four years since it was founded by the late Clifford W. Beers. Other officers include Dr. Frank Fremont-Smith, New York; Col. Leonard G. Rowntree, M. C., James R. Angell, LL.D., New York, and Dr. William L. Russell, New York, vice presidents; Dr. Adolf Meyer, Baltimore, honorary president; Mrs. Albert D. Lasker, New York, secretary; and Henry Pelham Robbins, New York, treasurer. G. Howland Shaw, LL.D., who retired recently as assistant secretary of state, was elected president of the American Foundation for Mental Hygiene at its sixteenth annual meeting, which took place during the luncheon session of the national committee. Mr. Shaw succeeds the late Dr. Bernard Sachs, New York.

Federation for Clinical Research—Dr Robert D Taylor, Indianapolis was chosen president of the midwestern section of the American Federation for Clinical Research during its annual meeting in Chicago, November 2, and Dr Frederick W Hoffbauer Minneapolis, secretary. Among the speakers at this meeting were

Dr Hoffbauer Serial Peritoneoscopic Examinations for the Study of Experimental Liver Damage in Dogs
Drs Walter H Sheldon and Abner Golden Atlanta Lesions of the Tubular Epithelium in Rabbit Kidneys Induced by Excessive Doses of Calcium Gluconate.
Drs Edward Massie and Anibal Roberto Valle, St. Louis Cardiac Arrhythmias Following Total Pneumectomy
Drs John S LaDue and Sandy B Carter Jr New Orleans Preliminary Study of the Efficacy of Maintenance Doses of Digitalis in Preventing the Recurrence of Congestive Heart Failure
Drs Charles Neumann Albert D Foster Jr and Emory A Rovenstine New York Peripheral Circulatory Response to Hemorrhage and Shock

Special Society Elections—Dr Mark F Boyd, Tallahassee, Fla., was chosen president of the American Academy of Tropical Medicine at its annual meeting in St. Louis, November 15. Other officers include Dr George W McCoy, New Orleans, vice president, Ernest Carroll Faust Ph.D. New Orleans, secretary and Col Thomas T Mackie M.C., treasurer—Dr Alvis E Greer, Houston, Texas, was chosen president of the southern chapter of the American College of Chest Physicians at its meeting in St. Louis, November 13-14. Vice presidents are Drs Carl C Aven, Atlanta, Ga., and Paul A Turner, Louisville, Ky. Dr Benjamin L Brock, Waverly Hills, Ky. was reelected secretary-treasurer—Major General Warren F Draper, on loan to the Army from the U.S. Public Health Service, was chosen president-elect of the Association of Military Surgeons of the United States during its annual meeting November 4 and Dr Irvin Abell, Louisville, Ky., was installed as president. Col James M Phalen, M.C., retired, Army Medical Museum Washington 25, D.C., is the secretary-treasurer. The 1945 session will be held in Detroit in October.

Mead Johnson Awards—Dr Fuller Albright Harvard Medical School, Boston received one of the Mead Johnson Awards presented through the American Academy of Pediatrics at its meeting in St. Louis in November in recognition of his studies on the skeletal and metabolic disturbances in hyperparathyroidism, hypoparathyroidism, rickets and other diseases affecting bone formation and the processes of calcification. The title of Dr Albright's address at the meeting was "Classification of the Causes of Osteomalacia in the United States." The second award in this group was presented to Dr Josef Warkany, Children's Hospital, Cincinnati, for his experiments on "animals in which he succeeded in producing congenital malformations in the offspring through the creation of specific vitamin deficiencies in the diet of the mother." The subject of Dr Warkany's address was "Congenital Malformations Induced by Maternal Nutritional Deficiency." At the annual meeting of the academy Dr Jav I Durand, Seattle, was elected vice president (president-elect) and Dr Joseph S Wall Washington D.C., was inducted into the presidency. Dr Clifford G Grulee Evanston, Ill., was reelected secretary-treasurer.

Postwar Anti-Leprosy Program—At a luncheon sponsored by the American Mission to Lepers at the University Club New York, plans were announced concerning the postwar antileprosy program, involving the expenditure of \$500,000 over a five year period to launch a planned and concerted attack on the disease. According to an announcement from the American Mission to Lepers the educational and training aspects of the problem concern every religious denomination and health or social agency that comes into contact with any of the millions of leprosy victims throughout the world. Among the speakers at the luncheon were William Jay Schiefelbusch Ph.D., Emory Ross, D.D., Dr Eugene R Kellersberger M.D. of New York, and Dr Jean Alonzo Curran, Brooklyn. The program will include the establishment of training centers for native Christian personnel in India, China, Burma, Belgian Congo, Ethiopia, Korea, Thailand and Liberia. The centers will be located wherever possible near leprosariums already in existence or awaiting construction. The trainees will receive thorough instruction on the subject of leprosy and will then move out into the towns and villages to carry on a program of health education, personal and community hygiene, medical care and treatment among the population. These workers comprising a steadily growing army to fight the disease will be drawn from schools and colleges, from among patients in whom the disease is arrested and from among healthy children or infected parents. They will be given scholarships and salaries. The medical consultants for the program appointed to date are Dr Harold W Brown, professor of parasitology, Columbia University College of Physicians and Surgeons New

York, Dr Jean Alonzo Curran Brooklyn, Dr Howard Fox New York, Dr Victor G Heiser Bantam Conn. medical consultant, National Association of Manufacturers formerly president, International Leprosy Association, Dr George W McCoy, New Orleans professor of preventive medicine and public health, Louisiana State University School of Medicine, Janet Welch Mackie of the Health and Sanitation Division Office of Coordinator of Inter-American Affairs, Dr Henry E Meleney, New York, and Col Richard P Strong M.C. adviser on tropical diseases Army Medical Center Washington D.C. The sum of \$450,000 is considered the minimum needed for the establishment and maintenance of the training centers for a period of five years. Increasing support from within the respective countries will be sought with the expectation that the work will eventually become self supporting and indigenous. The remaining \$50,000 will be used for a campaign of mass education through audiovisual materials adapted to the special needs of each area. Each project will be under the sponsorship of an established church agency. The denominations cooperating directly or indirectly include the Church of the Brethren, Congregational Christian Churches, Disciples of Christ Evangelical and Reformed Church, Lutheran Church, Mennonites, Methodist Church, Northern Baptist Convention, Presbyterian Church in the United States of America, Protestant Episcopal Church, Reformed Church in America, Society of Friends, United Church of Canada and United Presbyterian Church of North America.

Annual Forum on Allergy—The seventh annual forum on allergy will be held at the Hotel William Penn, Pittsburgh January 20-21. Among the speakers will be

Dr Ethan Allan Brown Boston A Review of the Literature on Allergy for 1944
Dr Samuel M Feinberg Chicago Factors Predisposing Toward Allergic Diseases
Dr Oscar Swineford Jr University Va Immunology of Pollinosis
Dr Louis Tuft Philadelphia Bronchial Asthma A Critical Review
Dr William F Petersen Chicago Responses of the Patient
Dr Lawrence G Beinhauer Pittsburgh Differential Diagnosis of Allergic Dermatoses
Dr Frederick M Jacob Pittsburgh Topical Treatment of Dermatitis
Dr Harry E Thorpe Pittsburgh Allergy of the Eye
Dr John H Mitchell and Rev F Charles Curren Ph.D. Columbus Ohio Nondirective Psychotherapy
Dr Mortimer Cohen Pittsburgh Pathology of Asthma
Dr Julius M Rogoff Pittsburgh Adrenal Function in Relation to Allergy
Dr George L Waldbott Detroit How to Avoid Emergencies in the Office While Attending Allergic Patients

The fifth annual forum lecture will be delivered Sunday afternoon by Dr Milton J Rosenau Charles Wilder professor of preventive medicine and hygiene emeritus, Harvard Medical School Boston, and professor of epidemiology University of North Carolina School of Medicine Chapel Hill on 'Serenity in Terms of Mental Allergy'. The forum will present its fifth gold medal for outstanding contribution to the development of knowledge of clinical allergy to Dr Rosenau on this occasion. There will be a forum on 'What Do We Know About Allergy to Foods?' with Drs Brown, Herbert I Rinkel and Orval R Withers, Kansas City, Mo., Charles H Evermann, St. Louis, Karl D Figley, Toledo, Milton B Cohen Cleveland and Dr Tuft. A feature of the meeting will be the announcement of the recipients of the Marcelle Award (THE JOURNAL, October 28 p 580). On Friday evening January 19 the Association of Allergists for Microbiological Investigation will also hold a meeting to review research and clinical experience. Six study groups have been planned for the forum's sessions with the following participants

Dr L Deff Henry Ann Arbor Mich Atopic Eczema in Childhood
Dr Robert Chobot New York Management of Asthma in Children
Dr Hal M Davison Atlanta Ga Food Allergy
Dr French K Hansel St Louis Management of Nonseasonal Allergic Coryza
Dr Eyermann Allergic Headaches
Dr J Warrick Thomas Richmond Va Ocular Allergy
Roger P Wodehouse Ph.D. Lerma N I Pollens
Dr Karl D Way Akron Ohio and Harry Iker Chicago Some Common Allergens and Where to Look for Them
Dr George E Rockwell Cincinnati Bacterial Allergy
Dr Frank F A Rawling Ann Arbor Mich Psychogenic Factors in Relation to Allergic Manifestations
Dr Theron G Randolph Chicago Food and Drug Allergy Diagnostic Changes in Total Leukocytes and Eosinophils Following Trial Ingestion
Dr Figley Some Common Allergens and Where to Look for Them
Dr Samuel J Levin Detroit Allergic Dermatoses
Dr Cohen Psychosomatic Aspects of the Allergic Patient
Dr Frederick W Wittich Minneapolis Immunologic Considerations in Allergy
Dr Leo H Cripe Pittsburgh Bronchial Asthma—Diagnostic Pitfalls and Their Relation to Therapy
Dr Harry L Rogers Philadelphia Iapamine Vitamin C Aminophyllin Penicillin and Ultraviolet Radiation in the Treatment of Allergic Diseases
Dr Homer F Prince Houston Texas Medical Economics as Applied to the Allergic Patient

New Unit for Plastic Surgery

A permanent practical memorial to the British War Relief Society of America is to take the form of a new wing of the Queen Victoria Hospital, East Grinstead, for plastic surgery treatment of the injuries of war. The work will continue in peacetime for those who suffer industrial injury. A year ago, to mark its fourth anniversary, the society expressed a desire to build and equip what will be both an instructional center and a modern operating clinic. Mr. Bertram Cruger, the chief representative of the society in this country, had seen for himself at the hospital what was literally the remaking—physical and mental—of British and Allied airmen disfigured by war injuries. Great work in plastic rehabilitation has been accomplished at this hospital. For three years a policy of expansion was pursued under the stress of a flood of patients. In 1942 it was decided to construct a thoroughly modern surgical unit at a cost of \$150,000. It was decided that four operating tables housed in separate rooms, with galleries for students, were the minimum required.

The establishment of this unit, the only one in England with promise of a permanent future, will make certain that the stagnant years which followed the last war will not be repeated. But plastic surgery is only part of the battle of restoring the physically disfigured and mentally shocked men to a competitive place in civil life. Occupational therapy is also practiced at the hospital. Badly burned airmen who form a large proportion of the patients are encouraged, often in the earliest stages of their recovery, to try their hand at fashioning small component parts of aircraft. Thus their interest is immediately aroused.

The Prevalence of Dental Disease Proposed National Dental Service

Concern at widespread dental disease is expressed in an interim report of the International Committee on Dentistry issued by the Ministry of Health. The committee was appointed by the government to consider how a satisfactory dental service can be provided for the public as part of the proposed National Health Service, how enough dentists can be secured and how research in dental disease can be promoted. The dental condition of the population is found to be bad and the effect on general health bad. On an average 90 per cent of the men and 86 per cent of the women entering the army and auxiliary services have needed dental treatment on enlisting, 13.4 per cent of the men had artificial dentures and a further 10 per cent needed them. At three large ordnance factories a representative number of workers were examined. Only about 1 per cent were dentally fit without dentures. In children the dental condition is also bad. In Cambridge only 91 per cent of 5 year old children examined had naturally sound teeth. Of 10,000 Scottish 5 year olds only 1,000 were found free from caries, and on the average seven out of each child's twenty teeth were decayed or missing, about five of these being molars. Among 8,700 Scottish children aged 6-13 examined, the percentage of sound first permanent molars dropped steadily from 82 at the age of 6 to 20 at 13.

The committee, which consisted mainly of leading dentists, unanimously recommended that a comprehensive dental service should form an integral part of the national health service. To preserve the health of the mouth there should be regular inspection and treatment of any incipient defects, which should

be paid for not by the people as patients but by the community as a whole and be promptly available with a minimum of formalities. There should be a general practitioner dental service broadly analogous to the proposed general practitioner medical service. A special effort should be made to improve the teeth of expectant and nursing mothers, children and adolescents. The greater part of the population have no such relation with a dentist as is conveyed by the term "family dentist" and are ill educated and apathetic with regard to the care of the teeth. One difficulty is that there are not enough dentists for the proposed service, and the war has caused a fall in the number of dental students entering the profession to below 300 a year, which is about 150 less than the quota permitted by the Ministry of Labor under the war restrictions.

As it is important that dentists working in the public dental services should have cause for satisfaction, there should be no compulsion to enter it. Any dentist should be free to engage in it either whole time or part time. The proposals are not intended to interfere with the free right of everybody to seek his dental care through private arrangement.

Developments at the Royal Society of Medicine

Proposed enlargement of the quarters of the Royal Society of Medicine, which has outgrown its present accommodations, was described in a previous letter. Not only is the society much larger but it is also rendering new services, involving new techniques of providing information. Access to the library is given to any worker in or related to medicine whose need is demonstrated. Cooperation with other libraries is planned under the Central Medical Library Bureau, in which some thirty medical organizations are already interested. An ampler service of information is made possible by the photostat, the book film and the precision enlarger. For the benefit of medical officers overseas, the society has sent out thirteen sets of film reading equipment, including two to the United States, so that microfilms of important articles may be read on the war front. The library's equipment already includes apparatus for the preparation of book films and the photostat service is being augmented by a special camera which can make book films and can also make prints from these in sizes suitable for dispatch to fellows who have no film reading equipment. Medical organizations in liberated countries are being approached with the object of helping them to replenish their libraries and also filling gaps in the society's library.

Barbarous Treatment of British Prisoners of War by the Japanese

Sixty British survivors from among 152 prisoners of war rescued by United States naval forces after a Japanese transport had been sunk on its journey from Singapore to Japan have reached this country. Our people are shocked by grim accounts of cruel and callous treatment of prisoners of war by the Japanese. This was described in Parliament by Sir James Grigg, secretary of state for war. He said that there was no longer any doubt about the policy pursued by the Japanese military authorities toward prisoners of war in Burma, Siam, Malaya and the East Indies. But this information does not relate to Hong Kong, Formosa, occupied China, Korea or Japan, where conditions appear to be relatively tolerable, nor does it refer to civilian internees. The great majority of prisoners in Singapore and Java appear to have been moved early in 1942 to Burma and Siam. The Australians were crowded into ships' holds which had been horizontally subdivided so that ceilings were no more than 4 feet high. The prisoners from Britain were sent by rail to Siam so crowded that they could not even lie down during the journey. They were then marched some 80 miles. Subsequent movement in Burma or Siam appears to have been on foot, regardless of distance, weather or the pris-

oners' state of health. The British prisoners were set to work constructing a railway through primitive disease infested jungle over the mountain range between Siam and Burma. The conditions were terrible even for natives of the country. Such accommodation as was provided gave little or no protection against tropical rains or blazing sun. Worn out clothing was not replaced. The only food was a pannikin of rice and half a pint or less of watery stew three times a day. But the work had to go on without respite, whatever the cost in suffering or life. The result was an appalling death rate, of which the lowest estimate was one in five. The one redeeming feature is the high morale maintained by the prisoners. Tribute is particularly paid to the medical officers who were captured, who achieved miracles in looking after the sick and injured despite lack of essential medicines and equipment. The British government has made a strong protest to the Japanese through the protecting power.

Use of Quinacrine in Malaria

The resolution of the Board for the Coordination of Malarial Studies that no advantage, and possibly some disadvantage, would accrue to the armed forces if quinine or totaquine was to replace quinacrine (mepacrine, atabrine) for the routine suppression and treatment of malaria has been published (*THE JOURNAL*, August 5, p. 977). This resolution has now been considered in England by the Drug-Prophylaxis and Therapy Subcommittees of the Medical Research Council Committee on Malaria. The various items were discussed, and it was agreed that British experience and the extensive investigations carried out in Australia under the direction of Brig Gen N. Hamilton Fairley, led to the same conclusions as those reached in America. It is not possible during wartime to disclose all the extensive investigations on which these official American and British resolutions concerning the relative merits of quinacrine and quinine have been based, but with the return of peace this will probably be done.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, Oct. 31, 1944

Penicillin in the Treatment of Yaws (Spirochetosis)

First results in the treatment of yaws—a spirochetosis like syphilis—are reported by Drs. A. M. da Cunha, Area Leão, Nerv. Guimarães and Humberto Cardoso of the Instituto Oswaldo Cruz, Mangumhos, Rio de Janeiro. The investigators used penicillin as a new therapeutic agent against the disease. In 7 cases complete disappearance of the external lesions was obtained between the twelfth and the forty-fourth day of treatment and serologic reactions were negative on the sixtieth day in all cases. Observation of the patients is being continued, under immunologic controls, each eight days. The treatment uses only a mean dose of 200 Oxford units each four or six hours. The total dosage has varied from 9,600 to 52,000 units.

Megacolon

Brazilian studies on megacolon are not yet well known, even after the publication of a great deal of work in medical magazines. Some authors in South America have pointed out important knowledge obtained by Brazilian researchers on the pathogenesis and etiology of this disease. Some aspects of megacolon were recently reviewed by Dr. Raymundo Britto of Rio de Janeiro, who observed good results in 2 cases treated by the vitamin B₁ therapy. The author presented the following conclusions:

Dolichocolon and megacolon are always associated and can not be separated for clinical therapeutics.

One cannot deny the possibility of maternal avitaminosis producing megacolon.

It is not possible to differentiate congenital megacolon from one that is acquired.

Delayed dolichocolon produces megacolon within time, this perhaps being the first step or the first phase of megacolon.

The Etzel theory of the etiology still stands; Hirschsprung's disease has the same etiopathology as acquired megacolon.

Early diagnosis is necessary, thus allowing treatment of the initial phase—that is, when symptoms are mild.

One case of dolichocolon and 1 of megacolon were cured by vitamin B₁ therapy in high doses and food rich in the B complex vitamins. These cases are clinically, physiologically and anatomically cured.

The cure of megacolon may be obtained by vitamin B₁ when Auerbach's and Meissner's lesion of the plexus has not yet been evident.

It is easier to achieve the cure of megacolon in children than in adults, for with them the lack of vitamins has not lasted sufficiently long for an irreversible lesion of the autonomic nervous system to have developed.

For Better Health and Education

THE JOURNAL recently published information from Moscow about provisions adopted in Russia to encourage large families. In Brazil there is also a legal measure to support healthy childhood and provide a good education. Some institutions are obliged to pay their workers additional wages, a so-called family salary. Each worker receives his own wage for his occupation, plus \$2.50 for each child. This represents nearly a tenth of the normal base minimum salary established by the government. Thus when a worker has 10 children he receives double wages. This measure has a tendency to be adopted by employers in all industries.

A New Leprosarium

A new leprosarium has been opened at Roça Grande, about 12 miles from Belo Horizonte, capital of the state of Minas Gerais. The Roça Grande Leprosarium, which cost about \$100,000, has been outfitted to receive 100 patients. The Brazilian government is cooperating with the states in the construction of a network of leprosariums and preventoriums, one of the main features of the campaign now being waged against leprosy. During the year 1943 thirteen new leprosariums and five new preventoriums for healthy children of leprosy patients were opened. Brazil has about 45,000 patients with this disease, or 100 per hundred thousand of population, a prevalence corresponding roughly to that in Russia.

Marriages

HARRIS ALBERT WEISSE, Eagle River, Wis., to Miss Elmor Eells of Milwaukee in Coconut Grove, Fla., November 25.

SYDENHAM BENONI ALEXANDER, Charlotte, N. C., to Miss Frances Huger Allison of Columbia, S. C., October 28.

GUSTAF WALTER ERICKSON JR., Springfield, Mass., to Miss Martha Lake Adams of Norwalk, Conn., September 24.

ALAN CHURCHILL WOODS JR., Baltimore, to Miss Louise Huntington Cole of South Orange, N. J., October 21.

WILLIAM THEARLE STEELE, Augusta, Ga., to Miss Gertrude Roberta Urquhart of Waycross, September 14.

ROY OTTO SCHOLZ, Baltimore, to Miss Pearl Trogdon Huffman at Morganton, N. C., October 7.

HENRY C. RICKS JR., Jackson, Miss., to Miss Bettye La Verne Jarvis of Sylacauga, Ala., October 5.

RICHARD ALBERT BAGBY, Richmond, Va., to Miss Frances Otwell of Cumming, Ga., October 5.

THOMAS CARROL IDEN, Berryville, Va., to Miss Mae Oglesby Trench of Pulaski, September 26.

SAMUEL CECIL STANTON, Hinsdale, Ill., to Miss Erna Evelyn Koellner of Chicago, December 16.

EDWIN C. SEGARD to Miss Patty Lechner, both of Billings, Mont., in Omaha, September 28.

Deaths

Maurice Lamm Blatt * Chicago, Rush Medical College, Chicago, 1903, professor of pediatrics at the University of Illinois College of Medicine, professor of diseases of children at the Cook County Post-Graduate School, specialist certified by the American Board of Pediatrics, member, and from 1935 to 1939 chairman for Illinois, American Academy of Pediatrics, in 1934 chairman of the section on diseases of children Illinois State Medical Society, president of the Chicago Pediatric Society, 1927-1928, veteran of the Spanish American War, Philippine Insurrection and World War I, served as lieutenant colonel and executive officer of the 108th medical regiment, Illinois National Guard, from 1926 to 1932, attending physician and director of pediatrics at the West Side Jewish Dispensary from 1902 to 1912, attending dispensary physician at the Chicago Municipal Tuberculosis Sanitarium from 1909 to 1912 and the Winfield Sanitarium for Tuberculosis from 1908 to 1915, attending physician, department of contagious diseases, from 1913 to 1918, later attending physician and head, since 1925, children's division, Cook County Hospital, consulting pediatrician, Illinois Eye and Ear Infirmary and Illinois Masonic Hospital chief of pediatric staff and for many years president of the medical staff, St Vincent's Infant and Maternity Hospital, attending pediatrician, St Joseph's Hospital, consulting pediatrician, Chicago Health Department, director of the Yankton (S D) College, died December 10, aged 65 of cerebral hemorrhage

Condon Carleton McCornack * Brigadier General, M C U S Army, retired Eugene Ore, Jefferson Medical College of Philadelphia, 1904, graduated from the Army Medical School in 1910, General Staff School in 1921 and the Army War College in 1925, honorary graduate of the School of the Line in 1920, entered the medical corps of the U S Army as a first lieutenant on April 23, 1910, subsequently advancing through the ranks of lieutenant colonel, colonel and brigadier general, retired May 31 1944 veteran of the Spanish-American War and World War I, instructor at the General Staff School, Leavenworth, Kan from 1921 to 1924 and at the Army War College, Washington, D C, from 1925 to 1929, at one time assistant commandant at Carlisle Barracks, Pa, where he had earlier served as instructor at the Medical Field Service School, for four years attached to the general staff in Washington having charge of the budget and legislative planning branch, received the Legion of Merit for 'exceptionally meritorious conduct in the performance of outstanding service' during World War II as surgeon and later as deputy chief of staff of the Fourth Army and the Western Defense Command, died in the Letterman General Hospital, San Francisco, November 5, aged 64, of coronary occlusion

Charles Langdon Gibson, New York, Harvard Medical School, Boston, 1889 emeritus professor of surgery at Cornell University Medical College New York, member of the American Surgical Association, Society of Clinical Surgery, American Association of Genito-Urinary Surgeons, International Surgical Association, International Urological Association New York Surgical Society and the New York Clinical Society, corresponding member of the French Academy of Medicine fellow of the American College of Surgeons during World War I served in France as a major and as director of Base Hospital number 9 for the American Expeditionary Forces served as attending surgeon first Cornell surgical division, New York Hospital, New York consulting surgeon, St Luke's New York City and Memorial hospitals New York, Vassar Brothers Hospital Poughkeepsie, South Side Hospital Babylon and New York State Hospital for Crippled and Deformed Children West Haverstraw formerly medical superintendent of the Winifred Masterson Burke Relief Foundation White Plains, N Y, died in New York Hospital November 24, aged 80

Reuben Martin Pederson * Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis, 1906, fellow of the American College of Surgeons, in 1911 enlisted as a private in the medical detachment of the first infantry, Minnesota National Guard, and later was promoted to first lieutenant and major in the medical corps, during World War I served overseas with the 34th division as lieutenant colonel medical corps, U S Army, commanding the 109th sanitary train, on the staffs of the Swedish, Lutheran Deaconess and General hospitals died November 20 aged 64, of coronary thrombosis

Edward Peter Halton * Passed Assistant Surgeon, Lieutenant Commander, U S Navy, retired, Holyoke, Mass, Yale University School of Medicine, New Haven Conn, 1905 he entered the U S Navy Oct 15 1910 and retired Nov 4

1914, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology and the New England Otolological and Laryngological Society, on the staffs of the Holyoke and Providence hospitals, died October 18, aged 62, of cerebral hemorrhage

Leonard Apter, New Orleans, Medical College of Virginia, Richmond, 1940, served an internship at the Touro Infirmary and a residency at the Charity Hospital, where he died October 21, aged 35

Helen Book Babcock, Quilcene, Wash, University of Oregon Medical School, Portland, 1908, died October 20, aged 65

Charles M Bradley, Beckemeyer, Ill, Albany Medical College, Albany, N Y, 1887, died November 25, aged 80, of aortic stenosis

Herbert William Davis * St Paul, Rush Medical College Chicago, 1880, an Affiliate Fellow of the American Medical Association general examiner for the Northwestern Mutual Life Insurance Company for forty-four years, at one time company physician for the Jackson Mining Company, Naugeone Mich, had been connected with the Iron Ore companies at Fayette, Mich, and Two Harbors, Minn served on the staffs of St Luke's, St Joseph's and City and County hospitals died November 16, aged 84, of coronary thrombosis

Anna Christensen De La Motte, Brooklyn, Cornell University Medical College, New York, 1900, member of the American Medical Association, on the staff of the Williamsburgh Hospital, died October 22, aged 82

Charles Jacob Doneghy * East Chicago, Ind, Howard University College of Medicine, Washington, D C, 1928, died October 2, aged 45, of coronary occlusion

Henry Eugene Fifield, Calais, Maine, Maryland Medical College, Baltimore, 1907, died October 17, aged 65

Morris Friedman, Brooklyn, Baltimore Medical College, 1896, examining physician for a local draft board during World War I, formerly a pharmacist, died October 3, aged 87, of cerebral thrombosis and bronchopneumonia

William R Garver, Crawfordsville, Ind, Medical College of Ohio Cincinnati 1876 veteran of the Spanish American War, died September 3, aged 90, of mitral insufficiency

Moses Goldberg, New York Long Island College Hospital, Brooklyn, 1907, member of the American Medical Association died October 4, aged 61

Warren Parker Grimes * Hillsboro N H, Harvard Medical School, Boston, 1891, an Affiliate Fellow of the American Medical Association, died November 13, aged 76, of coronary thrombosis

Harry H Hagey * Chicago, Northwestern University Medical School, Chicago, 1898, veteran of the Spanish-American War on the staff of the Evangelical Hospital, died November 15, aged 72, of coronary thrombosis

Crandmer Leland Hays, Collierville, Tenn, College of Physicians and Surgeons, Memphis 1908, member of the draft board of Tipton County during World War I died in the Baptist Memorial Hospital, Memphis, October 22, aged 59

Julius Goodwin Henry, West Blocton Ala, University of Nashville (Tenn) Medical Department, 1906, at one time on the staff of the New Britain General Hospital, New Britain Conn died September 29 aged 64

Daniel Noble Johnson, Decatur Ga, Georgia Eclectic Medical College, Atlanta, 1881, died October 18 aged 93, of traumatic pneumothorax and generalized arteriosclerosis

David Joseph Johnson * Boston, Harvard Medical School Boston 1897, veteran of the Spanish-American War formerly commissioner of institutions, died in the City Hospital October 7, aged 71 of cerebral hemorrhage

John Payson Kennedy, Atlanta, Ga, University of the City of New York Medical Department, New York, 1887, member of the American Medical Association, for many years city health officer, died October 24, aged 80

Benjamin Kinsell * Dallas Texas, Rush Medical College Chicago, 1901 on the staff of St Paul's Hospital, died October 16, aged 80 of uremia and pneumonia

John Patrick Kuhl * Butler, N J, Jefferson Medical College of Philadelphia, 1924, died in Pasadena, Calif Oct 6, aged 44

Elbert Alonzo Landman * Plaistow N H, Dartmouth Medical School Hanover, 1899 bank president on the staff

of the Benson Hospital Haverhill Mass, where he died October 18, aged 76, of Parkinson's disease

Paul Hudson Mahany @ Albion, N Y, University of Buffalo School of Medicine, 1930, served an internship at the Children's Hospital of Buffalo and Our Lady of Victory Hospital, Lackawanna coroner of Orleans County, died in the Arnold Gregory Hospital November 11, aged 44, of angioneurotic edema

Rush McNair, Kalamazoo, Mich, Chicago Medical College 1887 during World War I medical examiner of draft board number 2 in Kalamazoo president of the Kalamazoo Academy of Medicine in 1925 at one time member of the U S Pension Examining Board, participated in the founding of the Borgess and Bronson hospitals, died October 13, aged 84 of chronic myocarditis

Gilbert F McNitt, Racine, Wis, College of Physicians and Surgeons, Baltimore 1879, surgeon for the Chicago and Northwestern Railroad, on the staffs of St Mary's and St Luke's hospitals, died October 23, aged 90 of cerebral thrombosis

Warren Wesley Murfin, Patoka Ill Rush Medical College, Chicago 1884, member of the American Medical Association past president and secretary of the Marion County Medical Society, local surgeon for the Illinois Central Railroad elected to the school board of directors in April 1903 and served continuously as clerk of the board until April 1933 died October 16, aged 82, of arteriosclerosis

William Joseph Narey, New York University of the City of New York Medical Department, New York 1895 died October 13 aged 76 of heart disease

Charles William Rain, Knoxville Tenn Northwestern University Medical School, Chicago 1904 served during World War I on the staff of the Knoxville General Hospital, died in October aged 64, of generalized arteriosclerosis

Leonard Gabriel Redding @ Scranton Pa, Medico-Chiurgical College of Philadelphia 1908 formerly first vice president of the Medical Society of the State of Pennsylvania past president of the Lackawanna County Medical Society member of the House of Delegates of the American Medical Association from 1940 to 1943 on the staffs of the Scranton

CAPT DOMINIC PETER CARAVONA
M C, A U S, 1913-1944

LIEUT COMDR GEORGE LITTLE BUTLER
(MC), USNR 1910-1944

CAPT MARVIN COOKE
M C A U S 1915-1944

Charles William Merrell, Lubbock, Texas (licensed in Texas and Oklahoma by years of practice), died in O'Donnell September 24, aged 69, of acute dilatation of the heart

Stephen Douglas Moore, Van Alstyne Texas University of Louisville (Ky) Medical Department, 1884, member of the American Medical Association served on the school board for forty years died in the Baylor Hospital, Dallas, October 15, aged 84, of heart disease

State Hospital and the Mercy Hospital where he died October 5, aged 59 of carcinoma of the pancreas

Laura M Pratt Recher, Morocco Ind, Columbus Medical College Columbus Ohio 1884 died August 7 aged 87 of chronic interstitial nephritis

Allen Trousdale Reed, Loyah Texas Kentucky School of Medicine Louisville 1890 died in a Pecos hospital October 17 aged 81 of cerebral embolism

KILLED IN ACTION

Dominic Peter Caravona, Cleveland St Louis University School of Medicine 1938 served an internship at the St John's Hospital Cleveland, and a residency at St Charles Hospital in Aurora, Ill member of the American Medical Association commissioned a first lieutenant in the medical corps, Army of the United States on Aug 28 1942 later promoted to captain killed in action in the European theater of operations, September 25 aged 30

George Little Butler, Beaumont Texas University of Texas School of Medicine Galveston 1934 member of the American Medical Association served an internship at the Jefferson Davis Hospital and the Houston Tuberculosis Hospital in Houston formerly resident in surgery at the New York Society for the Relief of the Ruptured and Crippled commissioned a lieutenant (jg) in the medi-

cal corps U S Naval Reserve on Aug 8 1940 began extended active duty on April 2, 1941, later promoted to lieutenant and lieutenant commander, died in the Pacific area July 21 aged 34 of a gunshot wound of the right chest received in enemy action

Marvin Cooke, Auburn, N Y, Yale University School of Medicine, New Haven Conn, 1941, diplomate of the National Board of Medical Examiners, served an internship and a residency in pediatrics at the Strong Memorial and Rochester Municipal hospitals, Rochester, N Y, commissioned a first lieutenant in the medical corps, Army of the United States on July 17, 1942, later promoted to captain, died in the European area July 18 aged 28 of wounds received in action

Marcellus Reeves, Boston Harvard Medical School, Boston 1890 member of the American Medical Association died October 15 aged 81, of heart disease

Joseph B Ruffin, Powellsville, N C, University of the South Medical Department Sewanee Tenn 1898 member of the House of Representatives for Bertie County 1931-1932 for ten years coroner of Bertie County died October 15, aged 66

Albert Edward Sabin Ⓢ Dana Ind Medical College of Indiana Indianapolis 1897, Rush Medical College Chicago 1899 served during World War I, past president and secretary of the Parke-Vermillion Counties Medical Society on the staff of the Vermillion County Hospital, Clinton died October 26 aged 69 of angina pectoris and arteriosclerosis

George M F Scholz, Milwaukee Milwaukee Medical College 1903, member of the American Medical Association died November 1, aged 85 of coronary sclerosis and general arteriosclerosis

Oscar William Steinwand, Parlier Calif, Cooper Medical College San Francisco 1897 died October 14 aged 75 of chronic gastroenteritis

Steel Corporation, died in St Francis Hospital, Pittsburgh, November 23, aged 66 of lobar pneumonia and myocardial failure

Edward F Strohbehn Ⓢ Davenport, Iowa, State University of Iowa College of Medicine, Iowa City, 1891, president of the city school board from 1933 to 1941, on the staffs of the Mercy and St Luke's hospitals died November 11 aged 79 of cerebral hemorrhage

Samuel Sucherman, Chicago Chicago College of Medicine and Surgery, 1915, field health officer for the city health department from January 1916 until he resigned on Oct 21 1944 died November 8 aged 78 of coronary thrombosis

James Preston Temple, Shelbyville Tenn, Vanderbilt University School of Medicine Nashville 1878 died in a hospital at Nashville October 22 aged 88 of senility

John Adolf Vietor, Oyster Bay N Y, Columbia University College of Physicians and Surgeons New York 1911, formerly assistant professor of clinical surgery at the Cornell University Medical College New York, fellow of the American College of Surgeons associate attending surgeon at the New

"PUNISHMENT FOR VENEREAL DISEASE IN THE ARMED FORCES"

To the Editor—In the editorial in *THE JOURNAL* October 28 entitled "Punishment for Venereal Disease in the Armed Forces Ended by Congress," the editor is under a misconception and leaves a wrong impression on his readers.

The law S 1250 provides two essential features:

1 Repeal of the law providing forfeiture of pay due to venereal disease due to misconduct, and

2 Amending the veterans regulations defining line of duty and misconduct for pension and compensation purposes.

The editorial purported to show that all punishment for the acquisition of venereal disease, except under special circumstances (without leave, desertion status, and so on), has been rescinded and that venereal disease is now 'in line of duty' and not "misconduct." This is incorrect. The new law does not change the misconduct status for members of the armed forces but does eliminate loss of pay due to misconduct due to venereal disease. In other words, a service man with a venereal disease still has a "misconduct" status on his record and still has to make up for time lost in the sick bay for such disease but merely does not lose pay any more. On the other hand, for pension and compensation purposes the venereal diseases, except under special circumstances, no more represent a "misconduct."

Therefore, when the editor states that the service man infected with a venereal disease is now in the same status as one with any other acute infectious disease he is incorrect, since the service man still has a misconduct status on his record and must make up for time lost due to the venereal disease, which he does not have with other infectious diseases.

ISRAEL ZELIGMAN, Lieutenant (MC), USNR

PENICILLIN FAILURES

To the Editor—We read with great interest the communication of Drs. A. L. Bloomfield, M. M. Kirby and C. D. Armstrong in *THE JOURNAL*, November 11, on "A Study of 'Penicillin Failures'." Our own experience with subacute bacterial endocarditis supports their conclusion. We have had good results with a series of 10 successive unselected cases in which penicillin alone was given 200,000 to 400,000 units per day for three to nine weeks either continuous intravenously or intramuscularly every hour day and night throughout the entire course of therapy. (The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.) Seven of these patients have been discharged from the hospital and have been well up to seven months so far, the other 3 are still under treatment at this writing and are responding favorably. This was reported in preliminary fashion to the Central Society for Clinical Research on November 4. A detailed report of these cases will be published later. Emphasis on adequate dosage frequently administered to maintain continuously elevated penicillin blood levels and on the continuation of the period of medication for a sufficient length of time cannot be stressed too much if successful treatment is to be attained. We believe that the following of these rules will make penicillin an effective agent in subacute bacterial endocarditis.

SALICYLATES AND HEMORRHAGE

To the Editor—The paper "Hemorrhagic Complications with Death Probably from Salicylate Therapy" by C. T. Ashworth and J. E. McKemie published in *THE JOURNAL* November 25 rightly emphasizes the danger of hemorrhage that may result from the administration of salicylates. The conclusion of the authors that hypoprothrombinemia was a causative factor of the hemorrhage observed in their 2 cases may be questioned especially since no prothrombin determinations were recorded. While it is known that salicylates may decrease the prothrombin of the blood, it is still problematic whether the reduction is of such a magnitude as to cause hemorrhage. I have emphasized in even my early publications that the prothrombin must be reduced below 20 per cent of normal before there is danger of hemorrhage and that view now supported by clinical observation has been widely accepted. No clinical reports have appeared to show that salicylates even when given in massive doses, cause the prothrombin to fall to the hemorrhagic level.

It is known that various types of idiosyncratic reactions, including thrombocytopenic purpura, can occur following the administration of salicylates as well as of other drugs. It may well be that the 2 cases described by Ashworth and McKemie fall into this category, since their patients had petechial hemorrhage which is a characteristic lesion of thrombocytopenia. A conclusive diagnosis, of course, cannot be made without knowing the platelet count. In regard to the authors' suggestion that vitamin K is strongly indicated in all cases in which large doses of salicylates are administered, it should be remembered that it is based on assumption and not on verified data. To be sure, vitamin K can be given with impunity provided one is not led into a false sense of security and does not ignore the possibility that salicylates can cause hemorrhage in ways other than through prothrombin.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals Liability for Injury in Manipulating Bed—While the plaintiff, a woman aged 65, was a patient in the defendant hospital, a hospital conducted for profit, a nurse employee of the hospital attempted to lower the bed in which the patient was reclining by means of a mechanical device attached to the frame of the bed. The patient extended her right arm and unwittingly placed her hand beneath the metal bar as it descended and her third finger was crushed. To the metal frame of the bed there was attached a mechanical device which was operated by hand for the purpose of lowering or raising the bed on which the patient reclined. The device was equipped with a steel bar which entered a groove along the side of the metal frame of the bed. That lever or bar was ordinarily concealed from the view of the occupant of the bed by the mattress and bedclothes. The patient was not familiar with that contrivance and the nurse who observed the patient extending her arm while she was operating the hand lever failed to warn the patient of the danger, as she thought the patient was reaching with that hand toward a bedside table. Following the accident the end of the patient's finger was amputated, infection followed and as a result there was "considerable disuse of the finger on the end, and a definite loss of power in that hand." Subsequently the patient brought suit against the hospital alleging that the injury she suffered was due to the negligence of the nurse. The trial court which heard the matter without a jury entered a judgment for the patient and the hospital appealed to the district court of appeal, third district, California.

The hospital contended that the judgment was not supported by the evidence adduced at the trial, that the record shows as a matter of law that neither the hospital nor the nurse was guilty of negligence and that the plaintiff's injury was due solely to her own contributory negligence. We believe, however, said the appellate court that the judgment of the trial court is adequately supported by the evidence. As a paying patient the plaintiff was an invitee toward whom the defendant hospital was required to exercise ordinary care in providing a bed and attaching devices reasonably safe and free from danger. While it is true that a hospital is not an insurer of the safety of its patients it nevertheless owes them the duty to exercise ordinary care to see that the premises and equipment are in safe condition. It is also true that there is ordinarily no liability for injuries received from defects or dangers which are obvious and known to the injured person and which may be avoided by the exercise of reasonable prudence on his part. As is said in a note in 22 American Law Reports 341

It is well settled that the owner or proprietor of a private hospital or sanitarium which is operated for profit and is not a charity is liable in damages for injuries to patients due to the negligence of nurses or other employees.

In the present case, continued the court the dangerous device attached to the bed, by means of which the patient was injured, was unknown to her. The testimony of the patient makes it clear that she did not know how that particular device operated or that it was dangerous for her to reach out over the bed while it was being lowered. The circumstances of this accident indicate that it was a dangerous device. The patient had no knowledge of the operation or danger of the device and she had paid no attention on one occasion when the bed was previously raised by the device. It seems reasonably clear from the evidence that the bar which fitted into the groove of the frame at the side of the bed was at least partially concealed by the mattress and bed clothing. The trial judge saw the operation of the device and the manner in which the accident occurred by a demonstration at the trial. Under the circumstances the question as to whether the patient was guilty of contributory negligence because the device was obviously dangerous was a question for the determination of the trial judge with whose conclusion in that respect we may not interfere on appeal further as is said in 38 American Jurisprudence 866.

Contributory negligence is not imputable to a plaintiff for failing to look out for a danger which he had no reasonable cause to apprehend or to a plaintiff who was deceived by appearances calculated to deceive an ordinarily prudent person.

In the absence of knowledge to the contrary a patient in a private hospital has a right to assume that he or she will be provided with a bed and attached equipment for raising and lowering it which is reasonably safe and free from danger.

We believe continued the court that while the defendant hospital is not an insurer against any injury which may be received by a patient in the hospital there was sufficient evidence to support the finding of the trial court that the hospital nurse was guilty of negligence which proximately caused the accident by failing to warn the plaintiff of the danger of the descending bar when the nurse saw her reaching her arm in that direction. That negligence may be imputed to the hospital so as to create a liability on its part for the injury received on that account. The question under conflicting evidence as to whether or not the act or omission of the nurse employee constitutes negligence, whether or not the hospital or the nurse exercised the requisite degree of care for the safety of the patient under the particular circumstances here present and whether or not the hospital or the nurse should have foreseen the casualty and have protected the patient by adequate warning of a known danger, are ordinary problems for the jury or the trial judge. When there is substantial evidence to support the findings of the trial court on those issues, its conclusions may not be interfered with on appeal. In this case the trial judge determined those issues against the hospital, and this court is bound on appeal by the trial court's finding that the nurse was guilty of negligence.

Accordingly the judgment in favor of the patient was affirmed.—H. L. Sh. Meritt Hospital 151 P (2d) 17 (Calif 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Thiocyanate Therapy of Hypertension—Koffler, Freireich and Silverman present observations on 39 ambulatory patients with essential hypertension who had been treated for months or years with the usual therapeutic agents, so that the level of their blood pressures was known. After this period of observation potassium thiocyanate therapy was instituted. The authors used an aqueous solution of the drug in such concentration that 1 drachm contained 0.1 Gm and commenced with a dose of 1 drachm three times daily. After one week the patient was examined, the blood pressure recorded and a blood specimen obtained. Although in most patients the average blood level with this dose (0.1 Gm three times daily) was 5 mg per hundred cubic centimeters, as high a level as 15 mg per hundred cubic centimeters was obtained with this small amount. In cases in which there were signs of congestive heart failure, digitalis therapy and diuretics were continued. Such a regimen was not incompatible with the thiocyanate. About half of the 39 patients showed an appreciable lowering of the blood pressure, and a few others reported subjective improvement without lowering of the pressure. There was no correlation between the urinary output of thiocyanate and the daily intake or the blood concentration. No fatalities and no dangerous toxic effects were observed, because frequent blood thiocyanate determinations were made and in this way early toxic symptoms as well as the appearance of an abnormally high blood level could be detected and treated before dangerous symptoms supervened. Recent work of Caymess and his associates demonstrated that thiocyanates are naturally present in the body in a much higher concentration than any other known depressor substance. They suggest that the thiocyanates help to counterbalance the effects of the pressor substances in the body. A rapid rise in blood concentration is certain evidence of faulty excretion and cumulative action and indicates immediate cessation of the drug.

Congenital Subaortic Stenosis—Young reports 10 cases of subaortic stenosis which were discovered during the course of examining approximately 18,000 soldiers. This is an incidence of 0.05 per cent. The lesion appears as a firm, raised fibrous ring of tissue from 1 to 15 mm below the base of the aortic valve usually from 2 to 4 mm in height and extending 1 to 10 mm into the ventricular cavity. On microscopic examination, it is seen that this raised band, or shelf, is hyalinized connective tissue covered by intact, flattened endothelium. With Weigert's stain, the fibrous tissue has been shown by Wiglesworth to consist principally of elastic fibers. The patient with congenital subaortic stenosis usually has no symptoms referable

to the heart but auscultation and palpation reveal the murmur and thrill of aortic stenosis, with a normal or nearly normal aortic second sound, the sound is not affected because the lesion does not involve the aortic cusps but is situated below them. The blood pressure and pulse pressure are normal and consequently the anacrotic pulse of aortic stenosis is not present. With these observations, in the absence of a history of rheumatic fever or suggestive rheumatic attacks in a young patient, the possibility of subaortic stenosis should be suspected. Since most such patients eventually acquire bacterial endocarditis or die suddenly, persons with this disease should be rejected for military service.

Varices of Bronchial Veins as Source of Hemoptysis—Ferguson and his associates injected into the pulmonary veins particulate matter too coarse to enter the capillaries. Lungs fresh from necropsies were injected. A cannula was inserted into the pulmonary vein from the lower lobe, through which 500 cc of warm saline solution was forced to wash out the blood. The injection mass was then introduced through the cannula at a pressure of 80 mm of mercury. The injection mass consisted of white lead, cinnabar, sucrose, gelatin and water. The injection pressure was maintained several minutes after the lung was immersed in ice water, and then the injected lung was returned to cold storage to allow the mass to harden. The mitral stenosis cases had histories suggestive of rheumatic heart disease and necropsy confirmed the diagnosis. Eleven such cases studied by the injection method indicated the presence of direct venous connections between the bronchial and pulmonary veins in men of all ages. Mitral stenosis causes dilatation of the bronchial veins in the submucosa of the larger bronchi as a result of the establishment of a collateral flow through them. In mitral stenosis when infarction and acute pulmonary edema are not present, hemoptysis is probably due to bleeding from these dilated veins. Age, hypertension and arteriosclerosis do not affect the bronchial venous bed but some dilatation occurs in chronic congestive heart failure of long standing although the only lesion of the mitral valve may be dilatation of the valve ring.

- *Spontaneous Rupture of Rectus Abdominis Muscles. Result of Indirect Muscular Effort. I. J. Vidgoff—p. 132

Acute Spinal Epidural Abscess—Boger describes a case of acute spinal epidural abscess in a man aged 69. He was treated with a full course of sulfadiazine. The mild diabetes which appeared in this case is hard to explain. It is possible that the pancreas was involved by metastatic infection at the outset, when a septicemia must have existed which gave rise to the epidural abscess and the bilateral hilar kidney abscesses. A psoas abscess was visualized by x-ray nineteen days after the onset of pain. The abscess was drained. At necropsy there appeared to be no direct communication between this abscess and the pus exuding from the intervertebral foramen between the second and third lumbar vertebrae. Death seemed to be due to chronic debility secondary to the epidural abscess in the region of the cauda equina. Necropsy revealed a granulomatous inflammatory lesion which involved the epidural space throughout its circumference from the level of the second to that of the fourth lumbar vertebra. The abscess involved the anterior epidural space. Osteomyelitis may also have been

present. Spinal epidural abscess will be diagnosed more often if more practitioners become aware of epidural abscess as a cause of excruciating pain in the back, sudden in onset and accompanied by evidence of infection.

Spontaneous Rupture of Rectus Abdominis Muscle—Vidgoff presents 3 cases of spontaneous rupture of the right rectus abdominis muscle. All 3 concerned young men who had been in military service only one month. In all 3 the rupture occurred as the result of indirect violence due to sudden muscular contraction while scaling the wall on the obstacle course. All cases were treated conservatively with complete recovery. The question of surgery arises in cases of severe hemorrhage due to injury of the deep epigastric vessels.

Vaccination Against Oriental Sore—In 1942 Katzenellenbogen reported results of a systematic attempt to inoculate the inhabitants of a hyperendemic area against oriental sore. The region comprised settlements at the northern end of the Dead Sea. All settlers who had never been naturally infected with leishmanias and all newcomers remaining at the Dead Sea during the sandfly season were to be vaccinated. Thus a single sore would develop instead of the dozens of naturally occurring sores and the vaccination sore would be on an unexposed spot (10 cm above the knee). The inoculations were made with suspensions of cultures on Locke serum agar of *Leishmania tropica* isolated from local patients and of leishmania bodies of the same strain from the spleens of infected Syrian hamsters. Five hundred and fifty six persons were vaccinated against oriental sore, and 416 persons were followed up. A vaccination sore developed in 237 after an incubation period varying from less than a fortnight to eighteen months. This vaccination has considerably reduced the incidence in a hyperendemic region. Vaccination should be carried out four to five months before the sandfly season begins. As expected, there were cases of natural infection during the incubation period of a natural infection or natural infection during the incubation period of an artificial leishmania infection. Vaccination was found harmless even for infants, and practically painless. It gave the vaccinated persons a good chance of prophylaxis against numerous sores in exposed areas. Reactions after vaccination were due to a previous infection with *L. tropica*. Artificial reinfection was successful in 2 persons vaccinated immediately after the appearance of the first sore.

Treatment of Trichophytosis with Ethyl Chloride—Lewis and Morginson describe the exclusive use of ethyl chloride spray on 40 unselected consecutive patients with trichophytosis of the interdigital spaces soles palms or crural regions usually involving the toes and soles but occasionally also the hands and groins. Ethyl chloride produces immediate burning and stinging, particularly as the area defrosts. There was no

case in which treatment was discontinued because of this discomfort. Increased experience showed that proper technique of application is important. If liquid ethyl chloride runs onto the normal skin, particularly on the dorsa of the feet at the base of the toes, there results a dermatitis congelationis. These lesions were uncomfortable but healed uneventfully within three or four days. This complication from treatment is prevented by having the patient hold paper towels on the normal skin around the infected areas when the ethyl chloride is applied. The authors conclude that ethyl chloride spray, producing distinct frosting of the skin may be used without harmful effects in the treatment of trichophytosis. It may be applied to all varieties of lesions, including those showing secondary bacterial involvement. Immediate clinical improvement, with subsidence of vesicles and pustules healing of denuded areas, increased dryness of the skin and regression of hyperhidrosis, follows the applications of ethyl chloride. Ethyl chloride does not produce a cure or eradication of trichophytosis. Recurrences are experienced in practically all instances within ten days. Ethyl chloride may be used to advantage as an adjunct to the customary management of trichophytosis particularly in the vesicular stage. It apparently promotes dryness of the skin producing an antagonistic environment for the fungi.

Arteriosclerotic Hypertensive Fundus Oculi After Sympathectomy—Gans reports 18 cases of all stages of hypertension in which total or subtotal paravertebral sympathectomy was performed. The retinal vessels were denervated by stellate ganglionectomy. In the 15 patients who survived operation varying degrees of lowering of blood pressure were obtained. Studies of the fundi tended to confirm the beneficial effects of sympathectomy, since hemorrhages, exudates and papilledema disappeared, but it was significant that acute signs, such as vessel spasm and neural edema, persisted in a large majority of patients despite sympathetic denervation of the vessels of the eye. The degree of arteriolar sclerosis appeared to be of greater prognostic value than other retinal signs in evaluating the decrease in blood pressure to be expected after operation. Patients with the least retinal arteriolar sclerosis showed the best results after sympathectomy.

Nitrogen Metabolism After Fracture—Howard and his associates report observations on the nitrogen metabolism of 6 patients following fractures of the large bones of the lower extremity and results of comparative studies on 3 patients after operative procedures on the femur and on 1 after hemorrhaphy.

The patients with fracture were otherwise healthy, and the fractures healed satisfactorily. Balance studies were begun as soon as the patients' general condition permitted accurate collections of urine and feces, which varied from one to seven days after the trauma had been sustained. In the osteotomy cases it was possible to collect metabolic base line data preoperatively as well as to make observations immediately after the operation. Chemical determinations on urinary constituents were made, for the most part from aliquots of collections covering three day periods. At weekly intervals blood was withdrawn from brachial veins for the following determinations: hematocrit, serum protein, calcium, inorganic phosphorus, chloride, bicarbonate, nonprotein nitrogen, alkaline phosphatase and in some instances sodium and potassium content. It was found that vigorous healthy male patients suffering skeletal fracture treated by ordinary methods sustain large losses of body nitrogen during the early phase of their convalescence. The catabolic nitrogen, which is excreted in the urine, does not reach its maximum until six days after the injury is sustained, and nitrogen equilibrium is not reestablished for approximately thirty-five days. Repletion of the lost nitrogen was slow. The patients without fracture who underwent osteotomy sustained comparatively much smaller and shorter nitrogen losses and repletion was more rapid and vigorous. The authors concluded that disuse atrophy, bed rest, anesthesia, fever and infection do not account for the major part of the nitrogen losses. Sulfonamide compounds did not appear to influence the overall nitrogen metabolism in this group of patients.

Nephrectomy for Hypertension in an Infant—Semans reports the history of a boy of 2½ years. When he began to walk, at the age of 18 months, it was noticed that his abdomen was abnormally large. Eight months later he began to vomit. Examination revealed a palpable tumor in the left upper quadrant. At operation an ovoid tumor the size of a grapefruit was found on the left side of the abdomen in a retroperitoneal position. It was removed and was found to be a teratoma. Urinalysis one month later showed albumin for the first time. There was also some increase in urinary frequency. High blood pressure was discovered. Since on three occasions injections of diodrast outlined only the right upper urinary tract exploration of the left kidney was decided on. The removed kidney was the seat of a chronic pyelonephritis. The blood pressure changed from a maximum preoperative level of 200/134 to one of 98/62 three years after operation. The microscopic diagnosis of the lesion in the extirpated kidney was chronic pyelonephritis. Perirenal fibrosis seemed the most important etiologic factor in this case. This fibrosis resulted from the previous removal of the retroperitoneal teratoma.

Bacteriostatic Activity of Citrimin in Vitro—Timonin and Kovatt report investigations which were planned with the object of obtaining information concerning the bacteriostatic activity of citrimin obtained from the metabolism solutions of

Aspergillus of the Candidus group. It was found that citrimin exerts bacteriostatic activity on gram positive organisms only. Assay mediums containing 1 per cent dextrose demonstrated higher values of potency of citrimin than plain mediums. It was also demonstrated that citrimin obtained by different methods of purification differed in bacteriostatic potencies. Addition of fresh horse serum (5 per cent) to assay mediums resulted in reduction of the bacteriostatic potency of citrimin whereas para aminobenzoic acid did not interfere with it. Toxicity tests of citrimin in vivo revealed that 2 mg of citrimin proved to be lethal to 20 Gm mice whereas 50 mg per kilogram of body weight in rats resulted in no ill effect to the animals.

Constitutional Hepatic Dysfunction—Comfort and Hoyne think that constitutional hepatic dysfunction deserves further discussion, not because of its effect on the health of the individual, but because confusion with hemolytic disease, disease of the biliary tract and disease of the liver leads to unnecessary restrictions on activities of the patient and unnecessary surgical and medical procedures. The sole manifestation of the condition appears to be mild or latent jaundice. The essential pathologic finding is increased concentration of bilirubin in the serum, giving an indirect van den Bergh reaction. The jaundice may begin at any age and may be chronic or intermittent. It may be familial but is not always so. Constitutional hepatic dysfunction apparently does not produce symptoms other than the jaundice, nor does it affect the health of the individual. Hemolytic and hepatic diseases do not cause the jaundice and as the name implies, the jaundice is due to an inborn deficiency of the hepatic cells, chiefly with regard to their function of excreting bilirubin. It is a pure retention jaundice or an abnormally high threshold for excretion of bilirubin. It is an acholuric jaundice. The terms 'simple familial cholemia', 'simple chronic icterus', 'familial cholemia' and 'familial nonhemolytic jaundice' have been applied to the condition but the authors prefer the term 'constitutional hepatic dysfunction' because the term indicates the constitutional nature of the condition as well as the organ now believed to be responsible. The authors comment on 35 additional cases, which they reviewed from the records of the Mayo Clinic.

Absorption, Distribution and Excretion of Thiouracil—Williams and his associates describe experiments on rats and man relating to the absorption and excretion of thiouracil. They found that thiouracil is rapidly absorbed from the gastrointestinal tract and is readily excreted in the urine. With dosages ranging from 0.2 to 1.2 Gm daily, the concentration of the drug in the blood varied from 0.8 to 6.4 mg per hundred cubic centimeters, while the daily excretion in the urine varied from 16 to 618 mg. Most of the thiouracil in the blood is in the cells, the red cells containing a larger total amount but smaller concentration than the white cells. Patients receiving the drug for several days preceding death were found at necropsy to have some of the substance in essentially all the tissues of the body. Thiouracil was sometimes found in very large quantities in the bone marrow, thyroid, ovaries and pituitary while striated muscle testes and liver possessed relatively small concentrations. Adenomas of the thyroid possessed a much greater concentration of thiouracil than did relatively normal thyroid tissue. Cerebrospinal, edema and pericardial fluids were found to contain less thiouracil than did whole blood, the concentration in pleural and ascitic fluid was about equal to that of blood, whereas milk contained about three times as much. Thiouracil is rapidly destroyed by the contents of the stomach and the small intestine. It is also rapidly destroyed by many tissues of the body. No thiouracil is excreted in the stools. The colon bacillus does not account for its absence, since it does not destroy the drug.

Effect of Pregnancy on Renal Function in Women with Hypertension and Glomerulonephritis—Wellen and his associates report results of renal clearance tests during and after pregnancy on 6 women suffering from preexisting hypertension. On 3 of these who had been patients at the New York University Hypertension and Nephritis Clinic studies of renal function had been made before the advent of pregnancy. After

delivery, the patients were followed by further tests for periods of from one to four years. Two women with diffuse glomerulonephritis became pregnant while under observation. They exhibited edema, hypertension, proteinuria and hematuria for several months before their pregnancies began. The figures taken as normal were made up from averages obtained from 14 nonpregnant women and from 8 pregnant women. The authors observed an increase in renal blood flow when patients with hypertension became pregnant. This increase, as indicated by diodrast and phenol red clearance, appears to be real although slight in degree. In each of the 3 patients on whom observations of diodrast clearance were made before conception, the figures for blood flow were found to have risen during pregnancy. Similarly in all patients it could be shown that the blood flow fell after delivery. The glomerular filtration rate and the tubular excretory mass are unaffected by pregnancy in these women. Comparison of results obtained during pregnancy and after delivery indicate that pregnancy itself when uncomplicated by toxemia does not cause deterioration of renal function in women with essential hypertension or chronic glomerulonephritis. This failure to find signs of deterioration in renal function after pregnancy in women with essential hypertension or chronic glomerulonephritis is of practical importance in the handling of these patients. These observations run somewhat contrary to existing beliefs.

Cutaneous Response to Proteins of Hemolytic Streptococci in Rheumatic Fever—Taran and his associates show that the failure to establish a definite relationship between rheumatic disease and group A hemolytic streptococci has led most investigators to invoke a relationship to a specific type of hemolytic streptococci. Since one of the most sensitive responses to a specific antigen the antibody of which is sought for is the cutaneous reaction, the authors studied the reaction to the M fraction of twenty-five known Griffith types of hemolytic streptococci in rheumatic children, their normal siblings and normal children. The incidence of positive cutaneous reaction in normal children was 65 per cent, as compared with 83 per cent in rheumatic children. The incidence of positive cutaneous reaction in the normal siblings of these rheumatic children was the same as in rheumatic children. The cutaneous reactions of normal children were of a significantly milder degree than those of rheumatic children and their siblings, the highest degree of reactivity was found in the normal siblings of rheumatic children. The incidence and the degree of cutaneous reaction to the M fraction of hemolytic streptococci was not influenced by the age of the child, between the ages of 6 and 16, or by the rheumatic status. Active cases did not show a higher incidence or degree of cutaneous reactivity. The authors conclude that cutaneous reactivity to specific M fraction in rheumatic children diminishes only slightly with the lapse of time following an acute rheumatic episode.

Rubella Early in Pregnancy Causing Congenital Malformations—Erickson reports observations on 11 infants whose mothers had rubella during the first three months of gestation. Most of the babies were small and had considerable feeding difficulties. All had congenital eye defects and all but 2 had congenital heart defects. Cataract, generally bilateral, was the most frequent eye defect. None of the babies were cyanotic, and their cardiac observations on physical examination made it seem likely that the defect was a patent interventricular septum. In no case was there a family history of congenital ocular or cardiac anomalies. Important developmental changes are taking place in the eyes and heart early in fetal life and this coincides well with the occurrence of rubella in these mothers. Embryonic tissues are particularly susceptible to virus infections, this fact being made use of in the culture of viruses on chick embryos. It is conceivable that because of the smaller size of the filtrable virus it may pass the barrier of the chorionic villi more readily than larger infectious agents such as bacteria. Thus it seems plausible that a woman might have a mild systemic infection, such as rubella, might not be seriously ill herself and yet have serious injury occur to the developing fetus. The author thinks that girls should not be allowed to pass through childhood without having had rubella—a deliberate exposure at an opportune time would seem wise. He also discusses the justification for therapeutic abortion if rubella occurs during the first two months of pregnancy, because according to Swan's figures and his own 100 per cent of such babies will have serious congenital malformations. He recommends animal experiments with various types of viruses extending throughout the entire period of gestation.

Fibrocystic Disease of Pancreas—The report by Philipsborn and his collaborators is concerned with the clinical and pathologic findings in 26 proved cases of fibrocystic disease seen at the Children's Memorial Hospital in Chicago since 1938. In the early cases the condition was frequently erroneously labeled, some of the patients were thought to have bronchopneumonia, others were considered to be feeding problems. The disease is not uncommon. Pathognomonic lesions have been seen in approximately 35 per cent of the patients on whom necropsy has been performed at the Children's Memorial Hospital since attention was drawn to the syndrome. Fibrocystic disease has its inception in infancy, unlike celiac disease, which first becomes apparent during childhood. Ordinarily it manifests itself in one of three forms: (a) primarily in respiratory difficulties, (b) primarily in gastrointestinal disturbances and (c) in a combination of respiratory and intestinal difficulties. The patient is usually under 1 year of age. The mother brings the child to the physician complaining either of chronic cough and colds or of failure to gain weight. One of every 4 or 5 of these patients will have had a sibling who died in childhood of diarrhea,

pneumonia and malnutrition. Physical examination often reveals a high degree of emaciation, which is more striking when one has seen the enthusiasm with which many of these children eat. Studies of vitamin A absorption on blood drawn before and after the administration of 0.1 cc of percomorph liver oil per pound of body weight have assisted in diagnosis. Patients in whom pancreatic cystic fibrosis existed have had blood vitamin A levels that were under 30 units. The duodenal enzymes have been decidedly reduced both before and after stimulation of the pancreas. Absence or existence of a reduced enzyme concentration in the duodenum following secretin stimulation is significant. Fibrocystic disease is the clinical manifestation of extensive pancreatic cystic fibrosis. The antemortem diagnosis can be facilitated by realizing the various forms in which the disease manifests itself and by the judicious use of selected laboratory procedures.

Auscultatory Signs of Mitral Stenosis—During a study of 225 cases of 'potential rheumatic heart disease' and 'rheumatic mitral insufficiency' followed closely over a period of five to twenty-three years the auscultatory signs leading up to a final diagnosis of mitral stenosis in 17 cases were observed and described by Boone and Levine. In 12 of these cases a rumbling apical middiastolic murmur preceded by months or years the appearance of the classic presystolic crescendo murmur of mitral stenosis. In 10 other cases of the 225 a similar middiastolic murmur was subsequently found to disappear. The appearance of accentuation of the apical first heart sound and of the pulmonary second sound in rheumatic patients should stimulate the clinician to search more diligently for signs of valvular disease, but of themselves they are of little help in forecasting the development of mitral stenosis. Apical systolic murmurs of slight intensity and apical third heart sounds seem to have no practical implications. In adolescent and young adult rheumatic patients a definite diagnosis of mitral stenosis should be made only on the finding of a long rumbling presystolic apical crescendo murmur ending in an accentuated first heart sound. The

diagnosis may be suspected on the finding of definite apical middiastolic murmurs, but with the expectation that approximately half of these murmurs will disappear with further observation

Therapy of Burns—Roback and Ivy review studies which were undertaken to determine (1) whether a medicated pliable gelatin film possesses advantages other than the ease of application, and (2) whether the film disturbs or promotes the healing of burns. A uniform size excoriation wound, an excision wound and a third degree burn were made on each side of the back of dogs. The effect of several medicated preparations was compared by placing one of the preparations over the wound on one side of the back and another over the wound on the other side of the back. A 2.5 per cent sulfathiazole ointment, Pickrell's solution, which produces a film, and 10 per cent boric acid ointment were compared with a gelatin film containing 2.5 per cent sulfathiazole, some potassium iodide and enough glycerin and water to render the film pliable. A wound produced by removing the skin to the depth of the base of the hair follicles healed in the same time when treated with the gelatin film and the 2.5 per cent sulfathiazole ointment. With use of a loosely applied dressing the excision wounds healed in the same time when treated with the medicated gelatin film and the sulfonamide ointment, though the burn wounds healed somewhat more rapidly when treated with the medicated gelatin film. With use of a firmly applied dressing, the burn wounds treated with the medicated gelatin film healed more rapidly than those treated with Pickrell's solution. When the burn wounds were treated with the gelatin film and boric acid (10 per cent) ointment the healing time was the same. The incidence of infection was less with the medicated gelatin film than with the other medicated preparations used. But the extent of infection had no effect on the average healing time. Twenty-three noninfected wounds healed on the average in forty days and 29 wounds slightly infected for three or more days healed in thirty-nine days. A wound produced by burning heals less rapidly than a wound produced by excision. The evidence definitely shows that a firmly applied dressing decreases the time required for the complete epithelialization of a burn wound. Medicated gelatin covered with a medicated pliable sheet of gelatin and a firmly applied gauze or cotton dressing can be used for the treatment of burns and may prove to be more desirable than other preparations now used in the management of burns and extensive skin wounds.

X-Ray Diagnosis in Acute Pancreatitis—Metheny says that between 1931 and 1943 27 patients for whom a diagnosis of acute pancreatitis was established were admitted to the King

County Hospital, Seattle. The diagnoses were proved either at operation or at necropsy. The authors include 5 other cases in which they consider the diagnosis to be proved by the blood amylase and other typical conditions and by the x-ray films. There are essentially three roentgenologic signs suggestive of acute pancreatitis: (1) tender tumefaction of the pancreas, (2) changes in the stomach and duodenum, (3) evidence of ileus. The roentgenologic changes are predicated on the fact that the pancreas in acute disease is swollen to two or three times its normal size. It presses against the greater curvature of the stomach. The duodenum has lost its tone, and the fluoroscopist will be able to push barium sulfate into it, where it seems to hang and fails to be moved forward by peristalsis. Occasionally there will be enough gas in the stomach to give the characteristic outline of the greater curvature near the pylorus. More frequently there will show a fair-sized blob of gas in the cardia and another smaller one in the duodenal bulb. Also localized ileus, especially of the transverse colon or upper loops of jejunum, is observed. These x-ray changes were present when the patients were first seen and persisted as long as the disease lasted—in 1 case, twenty-one days after onset—and long after the blood amylase had returned to normal. In every 1 of the 32 patients, the onset was acute with nausea and vomiting. They had epigastric pain, but tenderness was often so slight as not to be noticed. Every patient had albuminuria so that absence of albuminuria would make pancreatitis doubtful. The patients might suggest a ruptured peptic ulcer, but they lacked the board-like rigidity. They might suggest an acute disorder of the gallbladder except for the fact that they were too ill, or an acute coronary thrombosis but for the slow or normal pulse rate and blood pressure. Nine patients with pancreatic edema were operated on, and 9 survived. Eight patients with pancreatic necrosis were operated on. Five died and 3 survived.

Role of Nucleus Pulposus in "Recoil" Injuries of Spinal Cord—Cramer and McGowan report the case of a soldier, aged 20, who struck his head while diving in shallow water. He died fifty hours after the accident. Necropsy revealed that the spinal cord was almost severed. Aside from the prolapse of the intervertebral disk, no abnormal vertebral protrusion nor gross tearing of any posterior ligaments could be demonstrated. On the basis of this case the authors advance what they believe to be an essentially new concept of the so called recoil injuries of the spinal cord. They believe that it is not the rather incredible excursion of a vertebral body virtually across the width of the spinal canal and back again but the violent protrusion of the intervertebral disk by means of the hydraulic ramlike action of the nucleus pulposus, or the rupture of the latter when subjected to sudden intense compressive force, which causes the damage to the spinal cord.

Neostigmine in Diagnosis of Pregnancy and in Treatment of Delayed Menstruation—The use of neostigmine as a diagnostic agent in determining pregnancy and in the treatment of amenorrhea was originated four years ago by Soskin, Wachtel and Hechter. Grossmann in 1942 reported 30 cases of either early pregnancy or delayed menstruation which were subsequently diagnosed or treated with neostigmine. Since then he has routinely administered the drug to an additional 100 patients complaining of menstrual delay. One cubic centimeter of neostigmine methylsulfate, 1 to 2,000 strength, was administered to each patient on three consecutive days. In some instances menstrual flow was precipitated after only one or two treatments thereby obviating the need for further injections. No untoward reactions from the drug were noted. The author stresses that the test is inexpensive, is simple to apply and does not require laboratory assistance for verification. Uterine bleeding will almost invariably result in cases of amenorrhea not due to pregnancy, of endocrine deficiencies or of gross pelvic disease.

Inhibition of Lactation by Hexestrol Dipropionate—Prescott and Basden point out that esterification of the estrogens retards their rate of absorption and elimination and thus prolongs their action in the body. Brownlee converted hexestrol into the dipropionate salt and found that by injection hexestrol dipropionate was one and a half to three times as potent as hexestrol when tested on rats. By mouth, hexestrol dipropionate was not so potent as hexestrol weight for weight, but the duration of action was twice as long. Hexestrol dipropionate was given to separate groups of women orally in tablet form and intramuscularly in oil but it soon became apparent that it was not so effective orally as parenterally, and the oral route was abandoned. The patients treated were those in whom it was necessary to inhibit lactation because of stillbirth, abortion, neonatal death or cracked nipples. No other treatment was given; the breasts were not bound up, no purgatives were used and fluids were not restricted. A single intramuscular injection of 12.5 mg of hexestrol dipropionate inhibited lactation in 29 of 44 mothers shortly after childbirth. When it was given within the first three days of delivery, lactation did not occur and there were no signs of breast engorgement or discomfort. Of the remaining women all but 1 ultimately responded to repeated injections. Only 8 required treatment for more than three days. A further course of injections to suppress secondary filling was necessary in only 3 (7 per cent) of the women. This compares well with the figure of 25 to 45 per cent for diethylstilbestrol. Hexestrol dipropionate, given intramuscularly in one or two doses, was effective also in suppressing lactation in 5 cases in which it had already been established.

Inactivation of Penicillin by Serum—Bigger presents results of experiments in which penicillin was titrated against *Staphylococcus pyogenes* in broth, in serum and in water. Both serum and blood inactivated penicillin; this inactivation varied greatly in degree with different samples of serum but was always much greater at 37 C than at lower temperatures. There can be no question that this inactivation is due to the presence in the serum or blood of penicillinase produced by penicillin resistant bacteria. Chain and Florey believed it to be a particularly fortunate property of penicillin that pus, tissue autolysates, blood and serum had no inhibitory effect on its activity. This statement has been repeated by other writers on penicillin. It originated in the paper by Florey and his collaborators in 1941 which records that incubation for three hours at 37 C of penicillin with blood and with slices of liver, kidney, spleen, brain muscle lymph gland, lung and intestine from the rabbit causes no detectable destruction. The author thinks that if human blood had been used and if the period of incubation had been extended inactivation of penicillin would have been detected. The author also cites observations by Rammelkamp,

Keefer, Fleming and others which give strong support to the belief that penicillin is inactivated in the body by contact with the blood. Penicillin administered intravenously, spreads from the blood vessels into the tissues. An investigation of the effect on penicillin of the tissue fluids might be valuable. The author concludes that penicillin is inactivated by contact with human serum or blood, the degree of inactivation varying greatly with different specimens of serum and being much greater at body temperature than at lower temperatures. This inactivation may lead to underestimation of the amount of penicillin in a patient's serum. Inactivation *in vivo* is probably important chiefly in cases in which excretion of penicillin by the kidneys is slow.

Constitutional Factor in Anesthetic Convulsions—Williams and Sweet report the results of electroencephalographic investigations on 22 patients of a series of 42 who had an anesthetic convulsion. The electroencephalographic investigation was carried out in all cases more than a month after the convulsion, and in most the interval ranged from one to two years. The patients were all in good health when examined and had had no further fits since the solitary anesthetic convulsion. Abnormal electroencephalographic records were obtained from about three fourths of these cases. Paroxysmal outbursts of abnormal waves were seen in over one half and larval epileptic attacks in a fourth. The incidence and nature of the different abnormal discharges seen were identical with those found in a large group of persons with idiopathic epilepsy and they did not result from the convulsion. There was no evidence from clinical observations in the 42 cases that the anesthetic convulsions differed in any respect from epileptic fits. All the evidence presented supports the view that anesthetic convulsions are primarily due to an inborn but latent epileptic liability. The factors which precipitate a convulsion in these predisposed persons vary among individuals, but many of the factors which have been incriminated are well recognized precipitants of epileptic fits in conscious subjects. It seems that the main difference between subjects of anesthetic convulsions and of idiopathic epileptic fits lies in the degree of predisposition to convulsions, factors which arise during anesthesia being merely precipitants of the convulsion.

Fluorine Content, Hardness and pH Values of Drinking Water and Dental Caries—During a survey of the incidence of dental caries in different parts of South Africa, 78,563 school children were examined. The number of children with caries in each city, town and district was expressed as a percentage. The fluorine content, hardness and pH values of drinking water of 109 cities and towns were determined. The mean fluorine content, hardness and pH values of 86 districts were calculated from the numerous analyses supplied by the South African Railways and Harbors, the Division of Chemical Services, and from analyses of samples submitted by the author. It was found that a highly significant relationship exists between

(a) the fluorine content of drinking water and the caries incidence rate (in the presence of fluorine in excess of 1 part per million the caries incidence rate is low, but in areas where there is much less than 1 part per million of fluorine the caries incidence is very high), (b) hardness of drinking water and the caries incidence rate. There is less caries where the water is hard and more caries where the water is soft. When the factors of the fluorine content and hardness act together, they influence the caries incidence rate in towns and in districts to the same extent. When the fluorine content and the hardness are each low, caries is far more prevalent both in towns and in districts. When the fluorine and the hardness are each high, caries is less prevalent. The higher pH (i. e. more alkaline) values of drinking water from the districts as compared with the towns appear to be significantly associated with the lower caries incidence rate in these areas. A high pH value, a high hardness and a fluorine content in excess of 1 part per million in drinking water together appear to be definitely associated with a low incidence of caries. On the other hand, when the pH value tends to be low, i. e. more acid, there is usually a low hardness and a low fluorine content. This is associated with a significant increase in the incidence of caries.

Extra-Articular Tibial Graft Plastic in Habitual Dislocation of Shoulder—Brun performed 65 operations for habitual dislocation of the shoulder on 63 patients. Most of the patients were young men including athletes, skiers, soldiers and hod carriers. In 50 operations he used the extra-articular implantation of a tibial graft into the neck of the scapula as suggested by Eden in 1918. He has abandoned opening of the joint and intra-articular graft plastics. He aims at the production of a bony abutment which prevents the slipping out of the humeral head. In the extra-articular implantation the tibial graft must be larger than in intra-articular grafting. He now uses a tibial graft 7 cm in length and 2.5 cm in width at its proximal end. In preparing the pocket for the graft he sees to it that it runs along the bone surface of the neck of the scapula and does not extend beyond the lower rim. This avoids the slipping in of the muscle mass of the subscapularis, and the graft will rest in its entire length on the bone surface and can merge with it. For the first eight days after operation, until the wound is healed the author fixes the arm to the body in adduction. After that he immobilizes the shoulder joint in abduction by means of a circular thorax-arm plaster cast for a period of six weeks. Abduction up to the full horizontal line has proved advantageous to regain quickly the complete function of the shoulder joint. This simple operation, which requires only about an hour, is superior to all other methods of treatment for habitual dislocation of the shoulder.

Cholinesterase Test in Toxemias of Pregnancy—Herschberg and his co-workers found that the serum cholinesterase content in pregnant and parturient women is not changed by undisturbed pregnancy and normal delivery. In the presence of pregnancy toxemia the cholinesterase content of the serum invariably shows an early decrease which is pro-

portionate to the severity of symptoms. As soon as the symptoms of toxicity subside, the cholinesterase content returns to normal values. A difference in excess of 0.4 cc of sodium hydroxide on titration is regarded as indicative of toxemia.

Cause of Late Puerperal Hemorrhages—In 9 cases of late puerperal hemorrhages, after 4 births and 5 abortions Palik and Rehnitz discovered that hyaline degeneration of decidual remnants was the cause. Degeneration probably began before delivery under the influence of trophoblast cells. The liquefaction and expulsion of the decidua probably failed to take place, because the fibrinous degenerated decidua does not elicit the round cell demarcation. The treatment consisted in instrumental removal of the remnants. After abortions, the earlier onset of menstruation may produce spontaneous cure.

 *Vitamin D Therapy in Large Doses and Calcium in Acute Rheumatic Fever A. Dosal—p 325

Vitamin D and Calcium in Acute Rheumatic Fever—Dosal gave vitamin D in large doses and calcium to 7 patients with rheumatic fever complicated by endocarditis. The disease was of acute, septic form with acute anemia in 2 patients. Vitamin D was given intramuscularly in doses of 15 mg for the first injection and of 7 mg for the second injection given two days later. Calcium lactate was given by mouth beginning the day after discontinuation of vitamin D₂ up to saturation. Improvement rapidly followed in all cases. Fever, perspiration, tachycardia and dyspnea were controlled. The patients were discharged from the hospital in satisfactory condition three weeks after admission. The improvement was permanent three or four months after discontinuation of treatment.

- *Practical Diagnosis of Active Pulmonary Tuberculosis I. W. Reichel—p 19
 Practical Microscopy for Physicians Review of Methods for the Study of Microscopic Material E. Schild—p 27

Diagnosis of Active Pulmonary Tuberculosis—Psychic symptoms such as weakness, easy fatigability, decreasing energy and reduced intellectual productivity may be part of the patient's subjective complaints. Subfebrile temperature may be observed in patients suffering with various chronic bacteremias and with mild disturbances of metabolism, but except in the vagotonic the temperature curve of patients with active tuberculosis may be differentiated from that in other diseases by the rise of from 0.2 to 0.5 degree centigrade in the afternoon as compared with the morning temperature. Rise in temperature associated with an increase in strenuous work, may be prolonged for at least two hours in patients with tuberculosis, in normal persons and in other diseases the temperature may be restored to normal within ten minutes to one hour. Pain, of which patients frequently complain may be considered as a symptom of active tuberculosis provided it is vague and mild. An increase in the number of the eosinophils occurs in exudative tuberculosis when the exudative process has passed its height. In proliferative tuberculosis this increase occurs simultaneously with the proliferation of the specific granulation tissue. An increase in the sedimentation rate occurs in exudative tuberculosis except where the absorption of the broken down tissue is prevented by encapsulation. As a rule the sedimentation rate is normal in proliferative tuberculosis but it may be temporarily increased in cases in which an aseptic nonspecific necrosis results from disturbances of nutrition due to the pressure of the proliferating granulation tissue on the adjacent vessels. Subcrepitant rales may be heard in cases in which the inhaled and exhaled air passes through the secretion. A tuberculous process isolated from the air passages may be silent. Changes in the respiratory sounds are heard on auscultation in cases in which consolidated tissue is interposed between the ear of the listener and the larger air passages. X-ray examination is the best aid to diagnosis of active pulmonary tuberculosis.

Book Notices

Segmental Neuralgia in Painful Syndromes By Bernard Judofich BS MD Instructor in Neurology Graduate School of Medicine University of Pennsylvania Philadelphia and William Bates BS MD F.A.C.S. Professor of Surgery Graduate School of Medicine University of Pennsylvania Foreword by Joseph C. Yaskin MD Professor of Neurology Graduate School of Medicine University of Pennsylvania Cloth Price \$5 Pp 313 with 178 Illustrations Philadelphia F. A. Davis Company 1944

Segmental pain and tenderness, or segmental neuralgia is defined by the authors as an area of spontaneous pain within one or more tender skin sensory segments, generally called dermatomes. Thus pain and tenderness may arise from any disease process, toxic absorption or mechanical disturbance which directly or indirectly causes irritation of the intraspinal or paraspinal elements which enter into the segmental distribution. Specifically these elements include the spinal roots before their exit from the vertebral column the dorsal root ganglions, the nerve trunks prior to their formation of the primary divisions and the soft structures close to the intervertebral foramina and nerve trunks. Repeated observations by the authors suggest that the combination of segmental pain and tenderness has its origin within or close to the vertebral column rather than in peripheral or referred visceral stimuli. Their purpose is to show that clinically the interpretation of pain can be greatly facilitated by eliciting hyperalgesic or tender skin zones which accompany the pain. The presence of tenderness and its distribution, whether local or segmental is of great aid in diagnosis and therapy. The work is based on the fact that clinically the combination of segmental pain and tenderness usually appears to be due to factors which irritate roots, ganglions or trunks of the spinal sensory nerves and not to painful impulses originating in diseased viscera. In other words, pain and segmental tenderness of the skin in most instances appears to be of somatic origin rather than of visceral origin. In the chest and abdomen segmental pain and tenderness may simulate the pain of visceral disease, and many patients who have submitted to medical treatment and surgical procedures are not relieved of pain until treatment is directed to the somatic origin of the pain and its cause. In the chest, segmental pain and tenderness is referred to as intercostal neuralgia. In the abdomen it has been called abdominal wall neuralgia. Other painful syndromes which are associated with segmental pain and tenderness include back sprains, scalp neuralgias, sciatic pain, brachial plexus pain, tic douloureux, scalenus anticus syndrome, herpes zoster and ruptured intervertebral disk.

The authors emphasize the diagnostic value of tenderness and devote much space to therapy, especially the technic of nerve infiltration, which in their experience has yielded the most satisfactory relief of pain. The source of back pain, in their experience is more accurately defined when approached not only from the point of view of localization by segmental tenderness but by distinguishing pain with tenderness from pain without tenderness. The patient with segmental tenderness also obtains more satisfactory relief of pain when massage heat or other modalities are applied to the spinal area rather than to the peripheral area of spontaneous pain. Paravertebral infiltration of nerve trunks is a valuable procedure in the relief of pain. The relief is more rapid than by any other form of therapy. This treatment should be reserved for pain of prolonged duration or for pain that cannot otherwise be controlled.

The authors emphasize the fact that while the complaints of the patient may lie within the distribution of the posterior primary divisions, tenderness of the anterior division is usually demonstrable and vice versa. The fact that a local infiltration of procaine into painful 'trigger points' gives relief of pain is not conclusive of the fact that these areas are the causes of the pain. Paravertebral infiltration in the same patient selecting the involved nerve trunks yields a much more satisfactory result. Although injections of irritant substances into areas of the buttock or of the back may cause acute pain in the leg or other areas they do not cause referred pain which is associated with segmental skin tenderness. The authors emphasize that

sympathetic or brachial plexus anesthesia will relieve pain whether or not a true scalenus anticus syndrome is present. The first prerequisite for acquiring proficiency in examining patients is to become familiar with the types of tenderness and the methods of eliciting tenderness. The pitcher plant distillate apparently is useful only in segmental neuralgia, which aside from the intercostal and trigeminal types, is rare. Its usefulness in meralgia paresthetica is doubtful. The authors specifically state that it is not of use in skeletal types of pain which rules out the neuritides, of which the disk syndrome is a specific type.

The choice of borrowed material is excellent especially that from Tilney and Riley, Labat, Foerster and Keegan. The book fills a need, that need being the integration of various poorly delineated painful syndromes. It should be of interest to every orthopedist, neurosurgeon, neurologist and anesthetist.

Os milagres do 'Padre de Poá'. Estudo científico. Relações com a medicina. O sobrenatural e a ciência. Por T. de Aguiar Whitaker médico psiquiatra do Serviço de Identificação do Gabinete de Investigações de São Paulo. Paper Pp 164 with 29 Illustrations. São Paulo The Author 1944.

In 1925 a dutch priest, Father Eustace Van Lieshout arrived in Brazil. After spending ten years in a sanctuary in Minas Gerais he moved to Poá, about 20 miles from São Paulo. Poá is a small village consisting of two streets leading to a square where the church stands. Adjacent to the church there is an artificial grotto with an image of the Virgin and a source of water flowing from under her feet. Poá offers to the tourist only the rudiments of civilization and under usual circumstances its population was not higher than a few hundred inhabitants. This situation was going to change under the magic spell of Father Eustace. The dutch priest began by gaining the confidence of his parishioners, and in the course of time he acquired the reputation of being a healer not only of souls but of bodies as well. This reputation grew later in such a way that the people of Poá came to consider him as a Saint and capable of working miracles. The news spread throughout the country and soon thousands of persons afflicted with the most varied diseases flocked to Poá after the miraculous power that was to cure their ailments. Father Eustace attended everybody the best he could. In an imperfect Portuguese he would first of all ask the patient whether he wanted to get well. Then he would say a simple prayer sometimes placing his hands on the afflicted region. On other occasions the patients would fill up containers in the fountain of the artificial grotto and after the water was made holy by the priest's blessing they would throw it on their bodies. The miracles performed stimulated big headlines in the newspapers and the degree of collective excitement rose to a tempo of hysteria. The floating population of Poá rose to 10,000 human beings who camped in the streets and country under the most unhealthful conditions and were exploited by profiteers and unscrupulous merchants. This alarming state of affairs came to a natural end when Father Eustace died on Aug. 30 1943.

In the first half of his monograph the author approaches the subject quite systematically gathering all available evidence on the cures such as witnessed by other people or by himself and also on the opinions that people from the varied cultural levels have on the case. Appended photographs give the reader a clear impression about Poá and its pilgrims the blessing of the miraculous water and the plain but attractive face of Father Eustace while performing his cure. In the second half the author enters into a thorough analysis of the miraculous or supernatural phenomena the Spanish mystics Lourdes, the Iguis and also of phenomena of metapsychology, premonitions, mediums, ectoplasms and the like.

Altogether Whitaker's book is a precious document which deserves to be read by both specialists and laymen.

Through Whitaker's descriptions and documents the reader gets a very vivid impression of the atmosphere of Poá in the years preceding Father Eustace's death. Such atmosphere would undoubtedly have supplied a writer of genius with invaluable material to write something comparable to what a medieval mystic or an Emile Zola wrote.

Queries and Minor Notes

BLOOD TRANSFUSION FOR GASTROINTESTINAL HEMORRHAGE

To the Editor—A consultant recently advised me to omit transfusions in bleeding gastrointestinal lesions provided the blood pressure is above 80 systolic because the transfusion might increase the hemorrhage. I will appreciate an authoritative opinion on this extremely important issue.

M D Massachusetts

ANSWER—Much has been said and written regarding the advantages and disadvantages of transfusion of blood in the presence of gastrointestinal bleeding. The fact remains, however, that this procedure, correctly applied, is the most important single means of saving life in cases of severe gastrointestinal hemorrhage. The contention that transfusion might increase or restart hemorrhage is based on the assumption that raising the blood volume and blood pressure dislodges the thrombus in the vessel. This phenomenon rarely is encountered in actual practice. Patients have died from lack of a transfusion of blood but apparently no case of fatal hemorrhage that actually was caused by transfusion has been reported. Various authorities differ concerning the indications for transfusion as based on clinical and laboratory data. A systolic blood pressure of more than 80 mm of mercury in the absence of symptoms and signs of shock does not necessarily indicate need of a transfusion if the systolic reading was within normal range before hemorrhage. As a rule if the systolic blood pressure falls to less than 70 mm of mercury, other things being equal, transfusion is indicated. In cases in which massive hemorrhage has occurred, repeated transfusions of whole blood have been given safely at the moderately rapid rate of 500 cc per half hour. Transfusion of whole or citrated blood at a rate of forty to sixty drops per minute can be performed without risk. In addition maintenance of fluid and electrolyte balance and proper nutrition is essential. In more recent years, estimation of total blood volume (total plasma as well as total cells) has furnished reliable criteria as to the indications for transfusion, the amount of blood required and the frequency of administration.

LONG CONTINUED ADMINISTRATION OF BARBITURATES

To the Editor—A normal healthy man aged 50 weighing 185 pounds (84 Kg) and 5 feet 7 inches (170 cm) in height has taken 1½ to 3 grains (0.1 to 0.2 Gm) of pentobarbital sodium nightly for the past ten years for insomnia. Physical examination was normal with repeatedly normal urine and blood examinations. What are the eventual deleterious effects? None are so far observable.

M D California

ANSWER—The chance of future deleterious effects in this man would appear unlikely. Even prolonged use of therapeutic doses of barbiturates in normal persons is not likely to be marked by discernible signs or only by slight slowing of physical and mental activity. Vertigo, ataxia, mild dementia or other symptoms may appear rarely. Unstable persons may show psychic aberrations, and those who react by inebriation tend to take the drug for that reason. The chief objection to the habitual use of barbiturates is addiction. Although withdrawal symptoms are rare, the subjects come to depend on the somnifacient drugs and fail to adjust their activities so that sleep occurs naturally, and then sleep does not come to them without the aid of this artificial sedation. Proper treatment for insomnia not of organic origin includes the solution of mental problems of the daytime which are carried over into the night. Even though the drug may do little organic harm it may prevent this desirable psychotherapeutic attention.

ADRENAL CORTEX AND DIABETES MELLITUS

To the Editor—Is there information regarding the effect of whole adrenal cortex, oxycorticosterone or desoxycorticosterone on the blood sugar level in juvenile diabetes or in the pituitary type of diabetes?

M C Kentucky

ANSWER—The islands of Langerhans are but one part of the body involved in the metabolism of carbohydrates. The liver and muscles are probably of equal importance, and certainly the hormones of the pituitary, thyroid, adrenals and sex glands play important parts. This is not taking into consideration neurogenic influences such as those originally described by Claude Bernard. The endocrine products of both the adrenal medulla (epinephrine) and many fractions obtained from the adrenal cortex are concerned with the regulation of the blood sugar level. No fraction known as oxycorticosterone has been described but three fractions have received considerable attention: desoxycorticosterone acetate, which has little if any effect

on carbohydrate metabolism, and corticosterone and fraction E (Kendall) both of which raise the blood sugar level. Soskin has reviewed the role of the endocrine in the regulation of blood sugar. Lukens and Dohan have discussed their findings as they pertain directly to the adrenal cortex. Other references which pertain to this relationship are also listed. Probably the best discussion of this subject has been that by Joslin in the *New England Journal of Medicine*. It may be said that there is a great need for detailed metabolic investigation of the role of fractions of the adrenal cortex in the metabolism of carbohydrates, but information on the subject has not yet reached the point where it is worthy of conclusions or clinical application.

AMINOPHYLLINE AND RENAL CALCULI

To the Editor—Recently 3 cases of renal calculi following the oral administration of aminophylline have come to my notice. Is it probable that there is a precipitation of this drug into the kidney pelvis? If so is it likely to be avoided by drinking lots of water and giving sodium bicarbonate with the drug?

Frederick J. Walter, M.D. San Diego, Calif.

ANSWER—There is no clear evidence in the published reports that aminophylline has been the cause of renal calculi. From a pharmacologic and chemical standpoint it is difficult to visualize how the excretory products of aminophylline could give rise to or augment the formation of renal calculi. It might be well to review these cases and exclude other agents, a chemical examination of one of the stones would be of interest. In any event the use of large amounts of water and sodium ion, in the form of sodium bicarbonate, greatly enhances edema formation and would thus defeat the purpose of the diuretic.

EDZEMA PROBABLY DUE TO HEART FAILURE—SENSITIVITY TO DIGITALIS

To the Editor—A woman aged 75 gets a pitting edema in the late afternoon which almost completely disappears over night. Her blood pressure is 140/70, the heart tones are somewhat flabby but there are no murmurs. I have tried support of the heart but each time digitalis is administered (1½ grains [0.1 Gm] of digitalis, any brand or 10 drops of tincture of digitalis a day) severe nausea and occasional vomiting follow the second dose. What can be given to support the heart? She rests every afternoon in bed.

Captain M. C. A. U. S.

ANSWER—Two questions are raised in this query. In the first place is there really congestive failure that needs digitalis or is there some other cause for the edema. It is important to establish the diagnosis with certainty. Cardiac enlargement should be found before edema due to heart disease is diagnosed. If the edema is due to constrictive pericarditis the heart need not be large but one should look for other evidence of the constriction. Otherwise a small heart means that the edema is of other origin for example, associated with poor local circulation in the legs with or without venous thrombosis.

The second question concerns the apparent sensitivity to digitalis. On occasion frail old ladies prove to be unusually affected by the drug, but if in this case a diagnosis of myocardial weakness with congestive heart failure is definitely established digitalis should be resumed in smaller dosage or squill in the form of urguin may be tried. On the other hand it is important to rule out a digitalis psychoneurosis which on occasion can induce a disagreeable reaction that is from a fear of the drug or a dislike of its taste. Another helpful measure in addition to rest and if indicated digitalis, in reducing the dependent edema would be a restriction of salt and fluid intake. In obstinate congestive heart failure when digitalis is per se insufficient or difficult to push then the diuretic drugs should be given.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE
DEPARTMENT, SEPTEMBER—DECEMBER 1944

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1933. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: 'BI,' Bureau of Investigation; 'E,' Editorial; 'C,' Correspondence; 'OS,' Organization Section; 'ab,' abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: 'Book Notices,' 'Deaths,' 'Medicolegal Abstracts' and 'Societies' are indexed under these titles at the end of the letters 'B,' 'D,' 'M,' and 'S.' State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under 'American Medical Association.' The name of the author in brackets follows the subject entry.

For author index see page 1226
